INDEX TO VOLUME XCVIII,
From January to June, 1909,

MINING AND SCIENTIFIC PRESS

	Page.		Page.
A		B	
Accounts for the Superintendent, Mine.....		Bahney, L. W.....Adjustable Pyrometer Stand.....	629
.....Harold Wilson.....	686	Baker-Burwell Dry Chlorination Process.....	241
Acetylene Mine-Lamps.....A. Cressy Morrison.....	155	Ballot-Sulman-Pickard Flotation Process.....	
Adams, W. J.....The Disaster in Italy.....	114Edward Walker.....	62
Ditto.....What Is an Ore?.....	548	Bantjes Consolidated, Johannesburg.....	375
Adjustable Pyrometer Stand.....L. W. Bahney.....	629	Consolidated Mines Company.....Company Report.....	635
Agitator For Cyanide Tests.....G. H. Clevenger.....	759	Bassett, L. F.....Smelter Fume.....	381
Agreement of Assays.....E. R. Rice.....	348	Beam Recrudescent.....Editorial.....	498
Alaska and the Yukon.....T. A. Rickard.....	15	Bean, George L.....Discharge Formulas for	
And the Yukon, Transportation Facilities in.....		Cast-Iron Pipe.....	666
.....W. M. Brewer.....	485	Bearing Metals.....	418
Building, A.-Y.-P. Exposition.....	793	Becker, Arnold.....The Engineer as a Financier.....	414
Mexican Gold Mining Company.....	177	Benito Juarez Mines Company.....	78
Progress in.....Alfred H. Brooks.....	193		
Yukon Exposition.....	493	Bergstrom, O.....Knudsen Process of	
Alaskan Coal Lands.....Editorial.....	464	Pyritic Converter Smelting.....	858
Alderson, Matt. W.....Three-Legged Trestle.....	393	Bingham, Utah, Boston Consolidated.....	
Alluvials, Nature of Gold in.....F. Lynwood Garrison.....	760Courtenay De Kalb.....	553
Aluminum, Uses of.....Bertram Hunt.....	515	Black Diamond, Crescent City, California.....	
Ditto.....J. T. W. Echevarri.....	424Oscar H. Hershey.....	147
Ditto.....Edmund Shaw.....	656	Blast-Furnace Tuyere.....L. S. Austin.....	392
Amalgamating Plates, Silver Coating of.....		Blasting and Preparing the Shots.....Dennis H. Stovall.....	699
.....W. A. Caldecott.....	92	Boiling Test for Cement.....	144
Amalgamation, Electrolytic.....J. H. Jory.....	445	Bosqui, F. L.....Short Zinc.....	478
Electricity as an Aid in.....Elmer Ellsworth Carey.....	249	Boston Consolidated Mining Company.....	
Electro-Chemical.....D. F. McGraw.....	891Company Report.....	526
Methods.....Lucius S. Pierce.....	216	Bradford, Robert H.....Mineral Resources of Utah.....	187
American Institute of Mining Engineers.....F. L. Clerc.....	346	Bradley, F. W.....Protection of Investors.....	85
Institute of Mining Engineers, Officers of.....		Bradley, Walter W., and Roberts, F. C.....Mule-Back	
.....Editorial.....	166	Transportation of Sectionalized Machinery.....	751
Securities Abroad.....Editorial.....	805	Brewer, W. M.....Transportation Facilities	
Smelting & Refining Company.....	73	In Alaska and the Yukon.....	485
Ditto.....Company Report.....	360	British Broken Hill.....Company Report.....	833
Amount of Principal and Interest.....	411	Columbia Copper Company.....Company Report.....	360
Amparo Mining Company, Etzatlan.....	139	Columbia, Progress in.....George A. Ohren.....	36
Amur Region, Steam-Shovel in the.....	731	South Africa Company.....Company Report.....	460
Andrews, E. C.....Broken Hill Silver Mine.....	158	Broken Hill Proprietary.....Company Report.....	763
Anthropomorphism in Petrography.....Edward K. Judd.....	700	Hill South Silver Mining Company.....	
Anvil Blocks.....	144Company Report.....	595
Appelbaum, M. E.....The Copper Outlook.....	91	Boston Consolidated, Bingham, Utah.....	
Arteaga District, Chihuahua, Mexico.....W. B. Winston.....	829Courtenay De Kalb.....	553
Ashanti Goldfields, West Africa.....Company Report.....	162	Broderick & Bascom's Tramway.....	163
Ashley, Harrison Everett.....Theory of the		Broken Hill Silver Mine.....E. C. Andrews.....	158
Settlement of Silme.....	831	Bromo-Cyanogen Process, Chemistry of.....S. H. Worrell.....	356
Asia Minor, Opportunities in.....Editorial.....	805	Brooks, Alfred H.....Progress in Alaska.....	193
Assay-Ton.....	612	Brown, R. Gilman.....Electric Counter-Balanced Hoist.....	282
Assays, Agreement of.....E. R. Rice.....	348	Ditto.....Tailing-Wheel v. Pump.....	478
Assessment Work.....	179	Brown, T. A.....Mechanical Elevator in	
Aubury, L. E.....California State Mining Bureau.....	347	Hydraulic Mining.....	613
Austin, L. S.....Blast-Furnace Tuyere.....	392	Browne, D. H.....Deep Lead Mining in Australia.....	445
Ditto.....Costs at the Osceola Mine.....	893	Browne, R. Stuart.....Short Zinc.....	718
Ditto.....Costs of Lake Superior Smelting.....	592	Buckland, Arthur C.....Dredging Industry in	
Ditto.....Furnaces for Melting Calcines.....	750	New Zealand.....	758
Ditto.....Lake Copper.....	582	Bumsted, E. J.....Mining Cost in Mexico.....	583
Australian, Deep Lead Mining in.....D. H. Browne.....	445	Bunker Hill & Sullivan.....Company Report.....	162
		Bureau of Mines, National.....Royal P. Jarvis.....	113
		Byron, E. L.....Special Machinery for Placer Mining.....	128
C			
Calabacillas Gold Mine.....Charles Walter Geddes.....	689		
Calcines, Furnaces for Melting.....L. S. Austin.....	750		
Calculation of Heat Conductivities.....Carl Hering.....	357		
Caldecott, W. A.....Precipitation of Gold			
by Carbonaceous Matter.....	828		
Ditto.....Silver Coating of Amalgamating Plates.....	92		
Ditto.....The Vacuum Pump in			
the Cyaniding of Sand.....	316		
California and Nevada, Eight-Hour Legislation in.....	559		
Historical Geology of.....William Forstner.....	853, 891		
State Mining Bureau.....L. E. Aubury.....	347		
Ditto.....James M. Hyde.....	214		
Dominant.....Editorial.....	364		
Calumet & Hecla and the Osceola.....	359		
Cameron, D. P.....Cost of Electric Pole-Line.....	113		
Cam-Shafts, Cushioning Vibrations of.....Thos. N. Miller.....	180		
Carbonaceous Matter, Precipitation of Gold by.....			
.....W. A. Caldecott.....	828		
Carey, Elmer Ellsworth.....Electricity as an			
Aid in Amalgamation.....	249		
Carr, Henry C.....Vein Structure in the			
Monument Mine.....	557		
Carter, T. Lane.....How It Strikes an American (I, II).....	447, 481		
Castillo, J. Cleoron.....Geology of the Platinum			
Deposits of Colombia.....	826		
Cement, Boiling Test for.....	144		

	Page.		Page.
Portland.....	John L. Howard..... 630	Ditto.....	Mount Boppy..... 635
Production in 1908.....	698	Ditto.....	Mount Morgan..... 360
Centralization of Gold-Recovery.....	375	Ditto.....	Mysore Gold Mining Company..... 595
Centrifugal Pump Efficiency.....	V. V. Messer..... 696	Ditto.....	Nipissing Mines..... 701
Cerro de Pasco, Sintering at.....	195	Ditto.....	North Butte..... 701
Chalmers, Alex.....	Power in Stamp-Milling..... 314	Ditto.....	Nundydroog..... 526
Chance, H. M.....	Contingent Fees..... 667	Ditto.....	Ooregum Gold..... 635
Ditto.....	The Engineer as a Financier..... 213	Ditto.....	Phelps, Dodge & Company..... 162
Ditto.....	Panama Canal..... 581	Ditto.....	Pioneer Company..... 162
Chances for the Prospector.....	H. H. Edgerton, Jr..... 479	Ditto.....	Pittsburg Silver Peak..... 460
Chapman, R. H.....	Symmetric Structure in Limestone and Lava..... 622	Ditto.....	Poderosa Mining Company..... 701
Chase, Chas. A.....	Finger-Chute..... 314	Ditto.....	Prestea Block A, Ltd..... 833
Chemistry of the Bromo-Cyanogen Process.....	S. H. Worrell..... 356	Ditto.....	Rio Plata Mining Company..... 526
Chihuahua, Mexico, Arteaga District.....	W. B. Winston..... 829	Ditto.....	Robinson..... 866
Santa Eulalia Mines.....	F. J. H. Merrill..... 37	Ditto.....	Round Mountain..... 701
China, Coal Mining in.....	Thomas T. Read..... 44	Ditto.....	Shwell Dredging..... 866
Mining in Northern.....	F. L. Cole..... 584	Ditto.....	Skidoo Mines Company..... 526
Chlorination of Sulphide Ores, Dry.....	F. W. Traphagen..... 522	Ditto.....	South Kalgurli Gold Mines..... 262
Churn-Drill Sampling.....	Carney Hartley..... 549	Ditto.....	Standard Consolidated..... 800
Ditto.....	W. E. Thorne..... 358	Ditto.....	Stratton's Independence..... 595
Chute, Finger.....	Chas. A. Chase..... 314	Ditto.....	Tonopah..... 833
Cinderella Deep.....	Company Report..... 701	Ditto.....	United States Smelting, Refining & Mining Company..... 833
City Ghosts.....	W. R. Lawson..... 432	Ditto.....	United Zinc..... 866
Clark, J. E.....	Re-Setting Tappets..... 748	Ditto.....	Utah Copper..... 763
Classification of Pulp for Tube-Milling.....	140	Ditto.....	Village Deep..... 866
Clerc, F. L.....	American Institute..... 346	Ditto.....	Vogelstruis Consolidated Deep..... 635
Clevenger, G. H.....	Agitator for Cyanide Tests..... 759	Ditto.....	Waihi Gold Mining Company..... 800
Cloverfield.....	Company Report..... 763	Ditto.....	Witwatersrand Deep..... 701
Coal in the Philippines.....	286	Ditto.....	Yukon Gold..... 294
In Rogue River Valley, Oregon.....	661	Competition, Smelter.....	Editorial..... 4
Lands, Alaskan.....	Editorial..... 464	Comstock, Theo. B.....	Protection of Investors..... 83, 182
Lands, Federal.....	Editorial..... 598	Concentrate in Western Australia, Treatment of.....	342
Mining in China.....	Thomas T. Read..... 44	Specific Gravity of.....	Edgar B. Van Osdel..... 667
Output in 1908, Utah's.....	898	Coniagas.....	Company Report..... 162
Volatile Matter in.....	634	Concrete in Mine Support.....	W. R. Crane..... 320
Coalfield in Kent, England.....	106	Conductivities, Calculation of Heat.....	Carl Hering..... 357
Coalinga District, Oil Measures in the.....	William Forstner..... 386	Confidence, Financial.....	Editorial..... 66
Ditto.....	R. P. McLaughlin..... 548	Conflict of Placer with Quartz Claim.....	319
Coating Cyanide Vats.....	R. H. Fraser..... 214	Consolidated Mining & Smelting Company of Canada.....	Company Report..... 262
Cobb, W. L.....	Fighting Fire With Snowballs..... 688	Contingent Fees.....	H. M. Chance..... 667
Cogswell, C. V. R.....	Cyanidation in Guanajuato..... 656	Ditto.....	Mining & Metallurgical Society of America..... 457
Coke, Moisture in.....	Editorial..... 804	Conversion Table of Metres to Feet.....	Lee Fraser..... 394
Cole, F. L.....	Mining in Northern China..... 584	Converter Smelting, Knudsen Process of Pyritic.....	O. Bergstrom..... 858
Ditto.....	Mining in Siberia..... 654	Cooling Towers.....	Samuel K. Patteson..... 668
Colima and Jalisco.....	W. A. Scott..... 254	Coon Butte.....	523
Collins, Henry F.....	Cornish Pumps and Pumping Engines (I, II)..... 289, 317	Co-Operative Topographic Surveys.....	George Otis Smith..... 851
Collins, W. F.....	Occurrence of Gold in Placers..... 850	Copper.....	Editorial..... 333
Collins, W. H.....	Montreal River District..... 895	District of Yerington, Nevada.....	665
Colombia.....	Editorial..... 201	In Low-Grade Ores, Estimation of.....	261
Economic Conditions in.....	F. Lynwood Garrison..... 550	Mine, The Utah.....	Courtenay De Kalb..... 516
Emerald Mines in.....	792	Mining at Ely, Nevada.....	Courtenay De Kalb..... 58
Geology of the Platinum Deposits.....	J. Ciceron Castillo..... 826	Mining Methods of.....	H. Lipson Hancock..... 730
Gold Mining in.....	F. Lynwood Garrison..... 217	Outlook.....	M. E. Appelbaum..... 91
The Real Eldorado in.....	F. Lynwood Garrison..... 29	Production in 1908.....	865
Travel in.....	Courtenay De Kalb..... 350	Range.....	Company Report..... 833
Colombian Health Conditions.....	J. R. Farrell..... 613	River, Alaska.....	53
Colorado Days, Early.....	George W. Maynard..... 789	Situation.....	James Douglas..... 10
In 1908.....	Forbes Rickard..... 26	Smelting at Lake Superior, Costs of.....	L. S. Austin..... 592
Tartuffe in.....	Editorial..... 267	Smelting Process, Fink.....	189
Colvocoresses, G. M.....	Mixed Geography..... 852	Statistics.....	Editorial..... 266
Company Report.....	American Smelting & Refining Company..... 360	Tendencies.....	Editorial..... 431
Ditto.....	Ashanti Goldfields, West Africa..... 162	Corkhill, Fred.....	The Nevada Meteorite..... 93
Ditto.....	Bantjes Consolidated..... 635	Cornish Pumps and Pumping Engines (I, II).....	Henry F. Collins..... 289, 317
Ditto.....	Boston Consolidated..... 526	Cost Sheet for Mines.....	Algernon Del Mar..... 782
Ditto.....	British Broken Hill..... 833	Costs at the Osceola.....	L. S. Austin..... 893
Ditto.....	British Columbia Copper Company..... 360	Milling.....	R. S. Handy..... 156
Ditto.....	British South Africa Company..... 460	Of Dredging.....	556
Ditto.....	Broken Hill Proprietary..... 763	Of Lake Superior Smelting.....	L. S. Austin..... 592
Ditto.....	Broken Hill South Silver Mining Company..... 595	Crane, W. R.....	Concrete in Mine Support..... 320
Ditto.....	Bunker Hill & Sullivan..... 162	Crater, Meteor.....	John B. Hastings..... 523
Ditto.....	Cinderella Deep..... 701	Crescens.....	Company Report..... 866
Ditto.....	Cloverfield..... 763	Creston Colorado Mining Company, Sonora.....	375
Ditto.....	Coniagas..... 162	Cripple Creek in 1908.....	W. W. Travell..... 41
Ditto.....	Consolidated Mining & Smelting Company of Canada..... 262	Creek, Ore Washing at.....	S. A. Worcester..... 291
Ditto.....	Copper Range..... 833	Crown Mines, Ltd., Consolidation.....	306
Ditto.....	Crescens..... 866	Crucible Assays.....	A. A. Steel..... 819
Ditto.....	Daly-Judge..... 360	Cullinan Diamond.....	155
Ditto.....	Esperanza, Ltd..... 800	Cupelling, Simple Control in.....	G. N. Pfeiffer..... 750
Ditto.....	Ferreira..... 866	Cushioning Vibrations of Cam-Shafts.....	Thos. N. Miller..... 180
Ditto.....	First National Copper..... 360	Cyanidation at Mercur, Utah.....	Leroy A. Palmer..... 616
Ditto.....	Goldfield Consolidated..... 262	In Guanajuato.....	C. V. R. Cogswell..... 656
Ditto.....	Greene Cananea..... 701	Lead Acetate in.....	C. M. Eye..... 82
Ditto.....	Guggenheim Exploration Company..... 360	Of Parral Silver Ores.....	H. T. Willis..... 488
Ditto.....	Kargurli Gold Mines, Western Australia..... 162	Of Silver Ores.....	Theo. P. Holt..... 546

EDITORIAL.

Greeting.

According to annual custom, it is my pleasure to-day to drop the impersonal 'we' of the editor and address my readers as man to man. Gentlemen, I thank you for your support; and Ladies, too, for I am glad to know that the partner of the mining engineer occasionally reads this journal. The year just ended has been full of incident, stimulating to thought and provoking comment. To some of the comment appearing in these columns you may have demurred. A man who is always in perfect agreement with his friends must be mentally colorless, and that were a pity, reducing life to a dreary monotone. Besides technical subjects, appertaining to the bread and butter of professional work, I have ventured to touch upon matters of national import and upon ideas that are superior to the narrow limitations of time and place. We mining engineers are more than artisans or day-laborers, we are citizens of the world. Man does not live by bread alone. The dry grain of technology needs occasionally to be moistened with the wholesome milk of human sympathy or the generous wine of national aspiration. The mining engineer and his brothers in metallurgy and geology are no narrow ascetics or shriveled hermits. We who belong to one of the broad-gauge vocations refuse to be stranded on the barren islands of specialized knowledge or marooned on the cold hill-tops of individual experience; all knowledge is our patrimony; all experience is our teacher. We feel the warm currents of human progress and breathe the vitalizing air of the loftiest human endeavor. The engineer is an integral part of a complex civilization; by scientific training, no less than by contact with every variety of mankind, he is sensitive to the pulses of the great tides of thought that wash the shores of Australasian seas, of the ancient civilizations around the Mediterranean, of the Orient that is now our farther West, of the re-awakening Spanish-Americas, of the little island to which "Fate, and the ocean, and some fostering star" have given continental significance. Human thought has never been less parochial; we no longer live by ourselves, whether as individuals or as nations; the wireless whispers of the air transmit every local happening, until nothing remains local. Threads of submarine communication are surrendered as we listen for aerial messages that pulsate round the earth, reaching not only those for whom they are primarily meant, but all in sympathy to record the vibrating thought of an intensely stimulating epoch. "The thoughts of men are widened with the process of the suns." The old problems are with us, truly, but they seem to have lost their pettiness in an application that gives them imperial importance. World-

wide movements of thought receive interpretation varying with latitude, but the meaning is the same. Mankind is striving to make the most of its heritage and to turn each possibility into golden opportunity. The individual desire is the national hope, whether in Venezuela or Germany, in Japan or Great Britain. The units refuse to be ciphers; the evolution of the race demands the adjustment to a new environment created by an extraordinary industrial development. To this dispensation the engineer belongs, in this drama he plays a leading part. It is for him to be an interpreter, not a supernumerary; to be an actor, not merely a scene-shifter; to prove that the recognition of fact does not forbid a noble faith; that he can industrialize his life without commercializing his soul.

T. A. RICKARD.

January 1, 1909.

SAN FRANCISCO, but lately lifting an ashen face from amid the ruins of a great disaster, gives the hand of sympathy to sufferers from the earthquake that has overwhelmed Calabria and Sicily.

REVIVAL of interest in West African gold mining has followed from favorable reports made by Mr. W. Broadbridge and confirmed by Mr. J. H. Curle, who has recently returned from the Gold Coast. In consequence of these reports the Consolidated Gold Fields of South Africa has agreed to provide capital for three of the companies in that region.

FOR THE PUBLICATION of this issue there are needed 110 reams of paper, weighing altogether not less than 5 tons. This consumption of wood pulp and rag is required to make the 11,000 copies that will be promptly distributed to the four quarters of the earth, for we have subscribers on the Arctic tundra and in the tropical jungle, at the University of Tientsin and at Columbia University, in Tierra del Fuego and in London.

THE PRESIDENT used a club to hit a carrion fly when he devoted a message to Congress to the denunciation of *The World* and its slanders. In such matters the impetuosity of Mr. Roosevelt carries him beyond the necessities of the case. But in denouncing the irresponsible periodicals that have made a byword of the American newspapers, he is doing a service. In time the public will recognize the mistake of surrendering their intelligence every morning to the ignorant and vicious scribblers of a debased form of ephemeral literature.

BRITISH mining companies have a plucky way of preferring re-construction to liquidation. When the mine shows signs of exhaustion the management begins scouting for a new mine on which to apply its unexpended capital and its unabated energy. Thus the Oroya Brownhill Company, owning one of the Kalgoorlie bonanzas, has sent engineers all over creation in the search for an attractive mining undertaking and has selected the La Leonesa mine in the highlands of Nicaragua. This

gold mine was first examined by Mr. Edmond N. Skinner and has now been recommended after inspection by Mr. C. S. Herzig. The profit assured from ore available is said to exceed the price for which the property is optioned. We are glad to see West Australian companies purchasing mines in the Americas.

REPORTERS, like kings, occasionally bestow the accolade of knighthood with impartiality, if not recklessness. Thus *The Spectator*, of London, recently spoke of Sir Winston Churchill, and even more recently *The Evening Post*, of New York, dubbed Mr. Moreton Frewen with a prefix that does not belong to him, although Sir Moreton seemed not unnatural, seeing that the Western press for years has so, incorrectly, entitled him. Neither Mr. Frewen nor Mr. Churchill is either knight or baronet, although both are clever men, well worthy to adorn the chivalry of the modern world.

COAL, like iron, is so basal an element of industrial development that any facts concerning the distribution of deposits of this mineral fuel are important. On another page Mr. Thomas T. Read, professor of mining in the University of Tientsin, gives the latest information regarding the known coal-bearing areas of China. Should the Celestial Kingdom wake up to modern progress and utilize its industrial possibilities, then these coalfields will become a decisive element of commercial growth and profoundly affect industrial conditions on the western coast of America.

WE CAN IMAGINE how soothing Mr. Carnegie's Scotch stories must have been to the Committee of Ways and Means when examining the spelling reformer on the subject of the price of steel rails. The Chairman might ask him what it cost to make steel and Mr. Carnegie would be reminded of a canny chield whom he met on the golf links at Skibo. The laird of the last mentioned castle would be smiling smugly at his own humor while the committee on the tariff would be yearning to throw a chunk of unprotected iron at the self-satisfied old Scotchman's head. He wrote magazine articles and then declined to testify on the facts.

ANYTHING coming from the pen of Mr. James Douglas is sure to be interesting, and when he tells us of the factors controlling the copper mining industry he will hold the reader's closest attention. Among other important matters he refers to the Producers' Committee, which is to be re-organized and come into active existence late in January or early in February. Incidentally, he explains the kind of combination this is to be—not in restraint of trade, but in establishment of sound business on a basis satisfactory to a maximum number. We are reminded of the Smelter Clearing House established at Denver about 15 years ago. Mr. Franklin Guiterman was the efficient secretary, and though a loose organization it served to distribute various classes of ores where they were needed, to the better attainment of an economical mixture at all the smelters.

The Producers' Committee will do a similar service for the copper mining companies, keeping them informed of the trade conditions and of the varying demand for the metal, so that the marketing of copper may be put on a safe and sane foundation.

LITIGATION over patents is always regrettable because it impedes the development of processes by throwing doubt upon the validity of the license under which a royalty is collected or exclusive privilege claimed. We note with pleasure that Mr. Edward Walker, our London correspondent, announces the conclusion of one stage, at least, in the legal controversy over the patents controlling the use of oil in the concentration of ores. As metallurgists well known to us are interested in both sides to this litigation we can take no pleasure in the victory of either, unless it leads to a compromise or a combination helpful to all concerned.

DURING the year 1908 ample evidence has been given of the gullibility of the greedy. Opera bouffe performances on the Stock Exchange, on the Curb, in the Press, testify to the attractiveness of the old lures and to the effectiveness of the old lies. Lawson, Goodwin, and Hawthorne have been the stars in the financial vaudeville of 1908. One of them was by profession an actor and made the most of the notoriety of the stage to entice play-goers into Nevada schemes for turning water into golden wine; another of these was by way of being a litterateur and lent a facile pen to meretricious descriptions of mines that were to make men rich over night; the third of the trio needs no description, he has been adequately exposed by his own impudent confession. In the advertisement of their schemes these spoofers have been aided by an irresponsible press that preaches morality weakly on one page and offers gold bricks luridly on another page. An old story truly, and the iteration of it is wearisome.

A REVIEW of progress in cyanidation, written by Mr. Alfred James, will be welcomed as the utterance of one who knows the details at first hand throughout the world, who is frankly committed to the introduction of patented devices, but who is broad enough to admit the merits of other systems and to bestow deserved compliments upon competitors. It is a pleasure to accord opportunity of speech through our columns to a man who gives freely from his own store of knowledge for the benefit of others. It is also pleasing to observe the growth of liberalizing tendencies in the metallurgical art. On this side of the Atlantic is Mr. James Douglas strenuously insisting upon the open door and free exchange of data among the smelters; from England comes the plea of Mr. Alfred James for co-operation among cyanide specialists, to the end that waste of effort may be obviated, so that many may not be found groping where the right road has been discovered. On the technical side, the most significant statements made by Mr. James refer to the abandonment of sand-leaching and the tendency to cease amalgamation, relying upon extraction from all-slimed ores. The prediction of 2000-pound stamps

reveals the tendency to reduction of costs through attention to mechanical details. This has long been the weaker end of gold-milling. Important also is his concession of the supremacy of the plain table as a concentrator for gold-bearing slime. It seems probable that the perfection of this method may receive increasing attention as a means for improving concentration of slime from all kinds of ore.

FROM NEVADA we have heard that Mr. Charles M. Schwab made some violent remarks concerning mining engineers who advised him to buy mines that failed to prove profitable. That was a year ago. He ought to have known better. "Like master, like man." We read that when examined by the Ways and Means Committee, now investigating the tariff, he was shown a letter written by himself nine years ago in which he advised Mr. H. C. Frick that the Carnegie Steel Company could make steel rails for \$12 per ton in defiance of foreign competition. Mr. Schwab, whom the daily press label a magnate, explained that he wrote that letter when youthful and sanguine. He said: "I wrote it at Mr. Frick's request, when he was preparing to sell out, and I wrote it entirely from the point of view of the manufacturing department." There were other items of cost that he had omitted, and these now, with the tariff endangered, he would be glad to add to the \$12. And this is the man who fumed and fussed when some of his supposed expert miners, themselves interested in the mining deals, were unfortunate enough to give him reports that proved too rosy in tint for the dry air of the desert.

AMONG the many useful actions of Mr. Charles E. Hughes, the Governor of New York, has been his appointment of committees to investigate alleged abuses in the administration of public organizations, such as banks and tramway companies. Even more timely has been the recent appointment of a committee of experienced men to examine into the methods of the Stock Exchange. Our readers will remember that a few months ago the brokerage firm of A. O. Brown & Co. failed dishonorably, and the members of the firm lost the privileges of the Exchange, because they created fictitious evidence of demoralization by selling blocks of shares having a value far exceeding their financial resources. They were expelled for trading when insolvent, but the authorities of the Exchange failed to make any comment on the case as a flagrant example of practices supposed to be frequent among brokers, namely 'wash' sales: an appearance of abnormal activity on the stock market is created by giving simultaneous orders for the buying and selling of shares of the same description in big amounts but nearly equal, so that on balance no large sum of money is involved. The semblance of excited business inveigles the outside public to come and buy, at rising quotations. By sales between brokers, by 'matched orders,' the transactions of the Stock Exchange are used as a lure to entice those who buy on a "bull movement" and to intimidate those—the same kind of simpletons—who always sell on a "bear raid." During

the Morse trial there was plenty of testimony in regard to such dealings in Ice stock and it was recorded that a syndicate of millionaires was formed in 1901 to create an artificial market for the Steel shares. There is ample ground for suspecting that the Stock Exchange is used by some of its members for chicanery of a base sort and that the National Bourse is sometimes only a casino where crooked games are played. Unfortunately, the Exchange plays a prominent part in the social organism of America and the least that we can ask is that it perform its necessary functions honestly, even honorably.

Price of Silver.

Silver mining has fallen upon evil days; the prophets and reformers find corresponding opportunity for the exercise of their respective talents. Mr. Theodore F. Van Wagenen, in this issue, ventures upon the dangerous function of forecast, promising a comfortable average price for the metal during 1909. No one is better equipped with knowledge on this difficult subject than Mr. Van Wagenen. Therefore it is interesting to observe that he is not befuddled by monetary theories, does not insist upon conspiracy among the Western nations to make the Oriental 'sink of silver' insatiably swallow more, nor does he propose to undo the work that cost Señor José Y. Limantour, the brilliant financial minister of Mexico, so many years of patient labor in his endeavor to give to Mexican currency the stability needful in a modern medium of exchange. He shows where the normal output of silver will be consumed, and on the simple principle of supply and demand, without artificial restrictions or subventions, deduces a price sufficiently high to sustain the existing producers at least. We hear nothing from Mr. Van Wagenen of a proposed change in the monetary standards of the East. China and India have their silver exchanges as we have ours for dealing in cotton and grain, and the flow and ebb of the great tide of brokerage is not unaccompanied by noises that sweep around the world. Just now the 'bears' have it their own way, but to think they wish to wipe out the trade on which they subsist is to misinterpret the Orient. The common people of the East know nothing of all this, and care nothing. They have their immemorial customs, and have not thought to question whether they be good or bad. Moreover, the Chinese tael is not a national coin; the Imperial Government does not monopolize the money-issuing function of sovereignty. Each Province strikes its own coin, so that no uniformity of weight or fineness exists. Each Province distrusts the others; all unite in distrust of the central Government; and the council of foreign powers profoundly distrusts the Chinese political machinery in its entirety. It must be observed that China could not, if she would, undertake a monetary reform without the consent and direction of the Western nations. It is brutal but true—the West holds China in its grip, as a creature to absorb its surplus products.

Constant rumors of declining demand from India

are not borne out by the facts. During 1908 the group of Indian principalities embraced under British rule imported a quantity of silver 4.3 per cent in excess of that absorbed in the previous year. The value of these importations, measured by Western standards, shrank 16.7 per cent, but it seems quite certain that the actual consumer was sweetly unconscious of this circumstance when he added the coin to his glittering hoard. The silver miner should bear in mind that he is to a large extent open to raiding by brokers on the exchanges of London and the East, with New York and other centres participating according to their ability. If Mexico also lay open to the spoiler, the fluctuations would be even more extreme and spasmodic. The market would surely rest on shifting sands. More is to be gained from national prosperity in that Republic, from internal improvements, and the growth of industrial stability, than from a temporary elevation of price through the free coinage of silver, which could not long endure. In short, we may persist in exploiting the Orient, but we can not continue exploiting Western nations that have enlisted in the cause of modern progress.

Smelter Competition.

In this issue we publish an article describing the conditions controlling the smelting industry in Utah. The author of the article, Mr. Courtenay De Kalb, was commissioned by us to make a special investigation into the factors that have brought about a crisis in the ore market of the West. For the situation at Salt Lake has more than local bearings; it has brought to a focus the irritation freely expressed for several years against the big smelter consolidation dominated by the Guggenheim family. The failure of the American Smelting & Refining Company to make a satisfactory contract with the Utah Consolidated Copper Company evidently hastened the decision of the Amalgamated people to enter the smelting business on a large scale. It has been announced recently from Boston that Mr. John D. Ryan, president of the Anaconda Copper Company, and Mr. Thomas F. Cole, president of the Greene-Cananea Copper Company, had joined with others in organizing the International Smelting & Refining Company, with a capital of \$50,000,000, which was largely over-subscribed. With Messrs. Cole and Ryan are William Rockefeller, of the Standard Oil Company, U. H. Broughton, who is son-in-law of H. H. Rogers, and president of the Utah Consolidated, W. E. Corey, of the United States Steel Corporation, and H. C. Frick, of Pittsburg. Heretofore, the Cole-Ryan coterie has engaged in speculations confined to copper mining enterprises, notably the Amalgamated group at Butte, the Greene-Cananea mines in Sonora, the Calumet & Arizona and other mines at Bisbee, and a number of smaller undertakings. They have avoided trespassing upon the preserves of the American Smelting & Refining Company or the other concerns controlled by the Guggenheims. Now we are told it is to be a fight to a finish; the new company is to build a smelter in Utah at once, and is prepared to erect or buy other plants as its business may require.

Thereupon, Mr. Daniel Guggenheim comes out with an interview stating that the Cole-Ryan people are welcome to any copper smelting that they want, the American Smelting & Refining Company has only one exclusive copper smelter in the United States, and looks upon copper smelting as "an extremely annoying business," preferring copper refining and lead smelting. Mr. Guggenheim adds that 90 per cent of all the lead ores available in the United States and Mexico is covered by ownership or contracts, and, therefore, any new smelting corporation will find it difficult to get this class of ore. Finally, it may be mentioned that the United States Smelting, Refining & Mining Company, controlled by Messrs. R. D. Evans, A. F. Holden, Edward Clark, and other energetic Bostonians, together with financial support from the Consolidated Gold Fields of South Africa, is doing well, having expanded its business both in Mexico and California. This, briefly summarized, is the smelter situation today. It invites further comment.

The Amalgamated company, controlled by the Standard Oil group, has done but little custom smelting in its Washoe plant, at Anaconda, or in its Boston & Montana smelter, at Great Falls. The Cananea smelter and other less important plants owned by this coterie, have been devoted to the treatment of copper ores and such gold and silver ores as made a suitable mixture. No lead smelting has been undertaken; the Guggenheim plants have had almost a monopoly of that field. Modifications and improvements in copper smelting, especially through cheaper roasting and better handling of every kind of furnace material, have lowered costs of copper smelting and increased the use of this kind of fire metallurgy as a basis for treating gold and silver ores that do not carry copper or lead. While lead was the usual collector for the precious metals in ores that were smelted twenty years ago, nowadays the scope of copper smelting in this regard has been enlarged. Moreover, the supply of copper ore has been enormously increased by the discoveries at Ely, Bingham, and Globe, while the source of lead ore has dwindled rapidly at Leadville, the great lead district of the past 25 years, leaving the mines of Missouri and the Coeur d'Alene as the principal producers. These are largely under the thumb of the Guggenheims and assure them a dominant position in lead smelting; in fact, the Guggenheim purchase of the Selby, Everett, and Tacoma smelters in 1905, was largely prompted by the desire to secure the contracts with such important producers of lead ore as the Bunker Hill & Sullivan, the Hercules, and the Federal group of mines, at Wardner, Idaho. To us it has always seemed a tactical blunder however advisable as a method of controlling the ore market, for the Guggenheims to have grasped the smelters on the Pacific Coast. As long as they were independent, the mine owners of the West could feel that they had an alternative market for their ores, and, having this idea, they were not restive under the domination of the Smelter Trust, as the American Smelting & Refining Company, controlled by the Guggenheims, had gradually become labeled. Fur-

ther, as long as the Smelter Trust was doing a strictly smelting business, there was no marked irritation, but when under the various aliases of the American Smelters Securities Company, the Guggenheim Exploration Company, M. Guggenheim's Sons, and so forth, this powerful group, reinforced by other shrewd financiers, began to purchase mines and to make contracts for the smelting of the ore produced by such mines, using such production as a means for further control of the metal market, then the mine operators, especially of the smaller defenceless type, began to growl in earnest. And who shall blame them? The American believes in freedom of opportunity and the career open to talent, but he is like any other intelligent human being in hating a 'cinch,' in objecting to a tyranny, whether political or commercial. Most of the time he is subject to both, but the subjection is nicely veiled and rendered as pleasant as circumstances require or as the Standard Oil Company, the Southern Pacific, or the Smelter Trust permits. So now the time seems ripe for competition, the conditions are ready for another big smelting company that shall smite the Guggenheims hip and thigh, and deliver the down-trodden, brow-beaten mine operator of the Great West! It sounds fine, but it is bitter irony.

Messrs. Rockefeller, Rogers, Broughton, Ryan, Cole, and the other Sunday-school teachers in that group of beneficent and patriotic citizens must smile at the outcry against the Guggenheims, and the use they have made of it for bearing Smelter stock, thereby making enough money to build their own smelter. The mine operator who expects the Standard Oil to do better for him than the Guggenheims is a simpleton. The Guggenheims may have made their yoke heavy, but the little finger of the Standard Oil shall be thicker than the loins of the present Smelter Trust. To paraphrase further from Hebrew history, the Guggenheims chastised the mine operators with contracts, but the Standard Oil will chastise them with rebates. The evidence given in the recent Federal prosecutions of the Standard Oil people has shown them to be the mildest mannered men that ever cut a throat financially or scuttled a ship commercially. No relief lies there. Competition may sober some of the men on the Guggenheims' staff who have been intoxicated by speculation on Wall Street, including several of the seven brothers, and the threat of reprisals from another powerful corporation may abate a little of the arrogance that unconsciously has crept into their late treatment of possible customers, but in the end any such fight as seems in prospect will end either by one predatory group gobbling up the other or a truce highly detrimental to the poor mine operator. Two courses are left to him: One is union for defence, the various individuals and companies that have ore to sell joining in an alliance for their general protection, with the intention of remaining loyal even at some sacrifice; the other is to watch the actions of the smelter corporations, and to invoke both State and Federal interference whenever acts in restraint of legitimate trade are suspected, to the end that they may be prevented and punished.

Go North!

When the world was startled by the output of gold from the North ten years ago, and when that output gave signs of dwindling, the question was asked: What is the outlook for mining in the interior region of the Yukon and Alaska? Mining engineers and geologists knew that the wonderful gold-bearing gravel of the Klondike, of Fairbanks, and of Nome were the result of a process of natural concentration that had been at work for thousands of years. They asked: Are the miners simply skimming the golden cream that can never be re-made, and will the mining operations soon end, leaving nothing but the skimmed milk of low-grade alluvial deposits? The answer is: While the geological dairy operates so slowly that its products cannot be made within the lifetime of the sons of men, it has been at work so magnificently in the past that even though the richest of the cream has been collected, there still remains a vast amount of wholesome milk. The alluvial deposits of the North are not worked out, nor will they be during the life of those now living.

This is an important fact, if true. Discussing the future of Alaska with an official who had good reason to take a friendly interest in the subject, the present writer was informed, last summer, that the placer camps were necessarily ephemeral, and that the future of the country depended upon the development of its copper and coal resources. Our informant had never been 'inside', that is, across the coast range into the spacious region drained by the Yukon, the Tanana, the Innoko, and the Kuskokwim; he was one of those to whom Alaska meant the southeastern province, from Ketchikan to Seward; to him the vague and vast tracts beyond the barrier of glacier and peak were the scene of an excited kind of nugget-hunting such as could not last; it had no industrial future; it was but the arena wherein adventurous spirits risked life and money in a search for rich patches of gold-bearing gravel that were soon garnered and never sown. He was hopelessly wrong.

To the traveler wishing to see a part of the world wholly unlike the beaten tracks, to be with men waging a fierce and cheerful fight with great natural obstacles, to live for a while with human-kind on the farthestmost frontier of civilization, where man in the unit dwarfs man in the aggregate, there is no more interesting journey than the tour from San Francisco to Skagway, over the coast range, down the 2000 miles of the Yukon, up to Nome, and thence homeward through the Aleutian archipelago. But it is no journey for a mere tourist; the time and the cost are wasted by anyone not in touch with mining or unable to appreciate the industrial conditions. The tourist wisely sails amid the lovely islands of the inland sea along the coasts of British Columbia and southern Alaska, and then goes by train from Skagway to the summit of the White Pass, getting a glimpse of the 'inside' from the mountain top, and then returns to his proper habitat. To the men of our profession, on the other hand, these northern mining regions must be intensely interesting, both

from a scientific and a commercial standpoint. The frozen condition of the ground and the factors modifying the arctic geology present problems new to most of us. The intelligent application of technology in overcoming regional difficulties, the wide distribution of gold in deposits of peculiar character, the labor problems arising in isolated communities, and the bending of every energy to overcome the delays and expense of transport—these are all tasks for the most adaptable of men, the modern engineer. And he can go there knowing that not only will he not risk his health, but he may even upbuild a physical system injured by the miasma of the tropics or the unwholesome life of a crowded city. The climate of the interior of Alaska is superb. Again we find that the average man gets his notions of the country as a whole from seeing a small and easily accessible portion of it. Southeastern Alaska, as typified by Juneau or Sitka, is a wet, misty, and rainy tract along a coast that catches all the humidity of the west wind from over the sea. This excessive moisture brings verdure and a scenic beauty that have particular charm; but it is not bracing to the physical part of man, and it feeds those glaciers with which even the well informed associate the name of Alaska. The southeastern coast is cinctured with rivers of ice; they are splendid spectacles; but once across the range the traveler sees no more glaciers; he is in an arid region, where the air is as it is at Tucson at 4 a. m. in March—that is, it is the air that creation breathed at the dawn of time, as free from microbes as interplanetary space, as stimulating as hope, as invigorating as youth, when "the world was young and life an epic."

Eldorado.

In this issue Mr. F. Lynwood Garrison introduces his discussion of the new mechanical subjection of Eldorado by a retrospect of the old days of adventurous conquest, which cost the lives of men, instead of the mere out-wearing of dumb engines and pumps and chains of buckets. He re-tells the story of the gilded chieftain of the Chibchas, and the golden treasure thrown, as a propitiatory offering to demons, in the lakes upon the plateau of what is now Colombia. That gold was actually cast into the lakes has been demonstrated by the recovery of many ornaments, but whether these were offerings to fancied demons of a supernatural order, or sacrifices made in preference to being looted by invaders from across the sea, is wanting in final confirmation. Some choice examples of aboriginal art in gold, which would have been of enormous value to archeology, were surreptitiously exported from Colombia several years ago and ruthlessly sent by the ignorant discoverers to the melting pot in New York. The legend of another gilded chieftain and ceremonial lake finally blended into that of the fabled Lake Parima and its golden city of Manoa situated on an island in the centre. So persistent was belief in the story that the maps for centuries showed such a body of water in the northern part of South America. Formerly it was

large enough to dwarf Lake Superior, and extended far up into Colombia; as exploration narrowed the limits in which imagination might play, the lake shrank and retreated eastward, resting finally in Brazilian Guiana. There it remained, even upon the school-maps of England and America, until about 1830, when the age of credulity had been so far swept away by devotion to fact that the simple word "unexplored" took the place of the dream-lake and its tempting city. Stories of the lake, of 'white' Indians, and of the gilded man persisted, however, in spite of incredulous geographers. It is interesting to find that usually some basis of fact underlies a persistent legend. This is a case of genuine folk-lore, all the more interesting because of its comparatively recent origin. Jules Creveaux penetrated the district in 1880, and then the truth was given to the world by a reputable and accomplished scientist. The 'lake' is a basin like the Tensas basin, for example, in the Mississippi valley, subject to annual inundation; the 'white' Indians are the Roucouyennes, a pale tribe, remarkable in having children born almost white, similar to the tribe of Ahuarunas in the upper Amazon valley, long known to ethnologists; and the 'gilded man' was found in the person of the chieftain, religiously daubed with clay, and sprinkled with brilliant mica scales obtained from a highly micaceous schist outcropping in the southern foothills of the Tumac-humac mountains. This rite was performed at the time of the approaching flood. Thus resplendent he would take his ceremonial bath. Even the propitiatory element was not lacking. News of these events filtered to the outer world through repetition from tribe to tribe, and kept alive vain hopes long after the real Eldorado had been spoiled of his golden store.

Metal Markets.

During the year 1907 the copper market suffered from violent fluctuations culminating in a low price for the metal early in 1908. Thus, Lake copper sold for 13 cents per pound in February, and for 12½ cents in March. With the exception of small variations, the market evidently was unable to lift itself until August, in which month general conditions became much brighter. Meanwhile, the general business of the country suffered tremendously. The steel industry had to bear the brunt of the depression, and early in the year the larger plants were being operated to hardly 35 per cent of their normal capacity. At this time the railroad traffic also decreased so greatly that 400,000 cars were idle. At every junction these cars stood like ghosts of dead business. The depression affected every trade throughout the country, and so many people in the United States were thrown out of employment that for the first time in its history the steerage accommodations of steamers leaving New York were overcrowded with emigrants returning to Europe. This exodus continued up to the last quarter of the year, when the tide of travel turned. It was only natural that the copper industry should bear its share of the general depression, particularly as the capital needed for

larger electric installations was no longer available. Conditions changed as the year advanced, and by October marked improvement was noticeable. This improvement culminated after the Presidential election, and a satisfactory business has ensued since November. Various circumstances, however, interfered with the further progress of this movement, and during the month of December there was a shrinkage, the closing prices of copper being about 14⅛ cents for Lake and 14 cents for electrolytic, with, however, a brighter outlook for healthy development of the market in the coming year.

Production was much curtailed last winter, but from May onward a great many of the mines that had been operated at a reduced rate gradually increased their production. New mines became active, mainly in Utah and Nevada, and at the moment, the production of copper is probably as large as it has ever been. There is every probability of this condition continuing during 1909, for there are no great fears of stocks accumulating. It is true, in Europe, the visible supplies, which about two years ago were below 10,000 tons, are now about 55,000 tons, but that is not at all a menacing quantity when one considers that this is the only reserve in the whole world.

Lead was one of the first metals to advance after the heavy reduction in prices during the panic. The year opened at about 3.50 to 3.60 cents per pound at New York; with an excellent demand, especially for white lead purposes, the market improved by leaps and bounds, until in July, when 4.60 cents was reached. The improvement, which was accelerated by a greatly reduced production, especially in the Western camps, could, however, not be maintained when during the year the mines were again operated in full, and from that time prices gave way from month to month. Since the hearings of the tariff revision have been resumed in Washington, with the probability that the duty on lead and lead ores may be reduced, buyers have become rather scarce, and this helped the declining tendency, the market closing barely steady at 4.10 at New York.

Manufacturers of spelter have had to go through a trying period. During last winter prices fell to about 3⅞ cents per pound at St. Louis and ruled in the first half of the year between 4 and 4¼ cents. Heavy stocks had accumulated, and while they were mainly in good strong hands and not pressed on the market, they exercised a depressing influence. At the same time ores were rather scarce, as it did not pay Western or Mexican producers to sell their product at the ruling prices, and in consequence the smelters had to pay more for the zinc in the ore than they could realize for the finished metal. Matters drifted along until late in the year, when the demand became much more active, and spelter advanced to about 5 cents at St. Louis. The stocks, which were estimated at the beginning of the year to be between 35,000 and 40,000 tons, are now reduced to about 12,000 to 15,000 tons, and as the production is still curtailed it is more than likely that the reserve will disappear entirely within the next few months.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

LIONEL LINDSAY is at Denver.
D. V. BURNETT is in the Transvaal.
J. R. FINLAY has returned to New York.
FRED. J. SIEBERT is at Las Vegas, Nevada.
BEN. S. REVETT spent Christmas at Denver.
R. GILMAN BROWN was in Germany recently.
J. M. CAIRNS has accepted an appointment in Chile.
JOHN A. PORTER is expected at Coronado, California.
T. A. RICKARD went to Pasadena on New Year's day.
THOMAS R. BARBOUR was in San Francisco this week.
D. C. JACKLING has returned to Salt Lake from New York.
HARRY S. PAUL has returned to Alameda from Nevada City.
J. H. CURLE was in Switzerland recently; he goes to Java soon.
J. W. SUTHERLAND, of Kalgoorlie, was in Scotland recently.
P. A. SATON has returned to London from the Malay States.
F. W. NOBS, of Mexico City, spent the holidays in San Francisco.
J. H. BATCHELLER went from Telluride to Boston for Christmas.
FRANK ELMORE was married on December 12 at Kensington, London.
F. C. CROCKER, of Hill City, South Dakota, was recently in Oaxaca, Mexico.
L. N. W. WARD has been appointed manager of the Attasi mines in West Africa.
J. HENRY RICKARD is examining antimony mines at Lake George, New Brunswick.
GEORGE A. GUESS is smelter superintendent for the Tennessee Copper Company.
R. RECKNAGEL is consulting engineer to the Oceana Consolidated Co. in the Transvaal.
PERCY GRAVE is mine superintendent for the Jalisco Mining & Smelting Co., in Mexico.
C. NOBLE CROWE is manager of the Lake George mines of the Canadian Antimony Company.
H. C. BELLINGER has been appointed manager of the Great Cobar smelter in New South Wales.
N. O. S. FORD has opened an office in Oaxaca, Mexico, to engage in mining engineering work.
SPURR & COX are now at 165 Broadway, New York. Branch offices are at Denver and Mexico City.
W. A. CARLYLE has been appointed professor of metallurgy in the Royal School of Mines, London.
J. H. CLEMES has sailed for South America to examine the Choicas mine in Chile on behalf of John Taylor & Sons.
C. W. PURINGTON spent Christmas at Brookline, Massachusetts; he sails for London on January 5.
DAVID GOODALE and A. F. HUGHES are examining mines near Carrville, in Trinity county, California.
J. V. N. DORR is acting as consulting engineer for the Golden Reward Mining Co. in connection with the remodeling of their slime-plant.
JOHN TAIT MILLIKEN, of Colorado Springs, has been made consulting engineer to the Golden Cycle Company, and A. L. BLUMFIELD has been appointed superintendent of the Golden Cycle mill.

The revenues of Mexico for the fiscal year 1907-08 amounted to \$111,771,867, and a surplus over expenditures resulted, reaching the sum of \$18,594,426. The aggregate surplus over expenditures in the Republic during the 13 yr. from 1895 to 1908 has been \$130,000,000. Out of this \$50,000,000 has been applied to internal improvements, and the remainder, or \$80,000,000, constitutes a reserve in the treasury.

GOLD AND SILVER PRODUCTION.

By courtesy of Mr. Frank A. Leach, Director of the Mint, we are enabled to give estimates of the gold and silver produced in the United States in 1908. Surprise will be occasioned by the fact that the total output of gold is greater than in the year 1907 by \$5,878,200. The increase in California is unexpected but cheering; it is to be credited in part to the dozen additional dredges that have been put

a gain, for Fairbanks has redressed the temporary decline at Nome, and outlying new mining districts have yielded contributions which in the aggregate constitute a respectable total. The Treadwell mines produced \$500,000 more than in 1907. In South Dakota there is a decided increase, traceable mainly to the Homestake's recovery from the fire underground, and to the improved methods of cyanidation. In silver, the total decrease is nearly \$10,000,000. Nevada shows a notable gain in quantity, although

The commercial value of fine silver in 1907 averaged about 66c. per oz.; in 1908, about 53c. per oz.
The production of fine silver in 1907 amounted to 56,514,700 ounces.

to work, in part to the cessation of the labor troubles that crippled mining on the Mother Lode in 1907, and finally to the additional gold recovered in the course of the enlarged copper smelting operations in Shasta county. The shrinkage in Nevada is easily accounted for, the rich group of mines controlled by the Goldfield Consolidated company having been in a condition of suspended animation pending the completion of the new mill. Moreover, the panic hit 'wild-catting' severely, and while that is not a profitable form of mining, it does contribute to the sum total of production. Alaska was expected to show

the value is less than in 1907 on account of the smaller price commanded by the metal in 1908. The mines of Tonopah are responsible for the result.
It is probable that the gold production of the world for 1908 was \$427,000,000, or about \$16,500,000 more than the year previous. This increase is due mainly to South Africa, where the preliminary estimate shows \$144,675,000, a gain of \$12,000,000. The United States holds the second place. Russia and Mexico both exhibit a slight increase, and the shrinkage in Australasia was only about \$2,000,000 in the year just ended.

THE COPPER SITUATION.

Written for the MINING AND SCIENTIFIC PRESS

By JAMES DOUGLAS.

The copper trade in the beginning of the year just closing had not commenced to recover from the shock it sustained in the previous October when the copper mining interests first became aware of what they should have known months previously—that the bottom had dropped out of the boom. Under the influence of the shock most of the Butte mines, the Cananea mines and, in Canada, the Granby Consolidated, and nearly all the small concerns in the United States and Mexico, suspended operations, producing in the meantime a shrinkage of production that helped to bring about a return to what, let us hope, will be a normal condition. During the winter months Anaconda remained shut down, and Cananea did not resume active operations until September. As a result, the manufacturing trade on both sides of the Atlantic was enabled to absorb practically the whole of the somewhat restricted output, and by the time these large concerns re-entered the market as producers, the gradual restoration of confidence, and corresponding healthy demand for copper, permitted these additions to the metal market being absorbed without disastrous effects upon the price. As the year closes, therefore, all the old large producers are again almost in full blast, and some new producers have entered the lists. The deficit from the suspension of some older mines has probably been fully met by contributions from Utah and Nevada.

The year's statistics will probably show a production not widely different from that of 1907. The production of the large mines in southern Arizona has been maintained quite up to the normal. The only producer in that region, including northern Sonora, which has enlarged its capacity, and correspondingly increased its output, is the Moctezuma Copper Co. The concentrate made in the new mill, where the capacity is from 1500 to 2000 tons of ore per day, more than double the capacity of the old concentrating mill that is now out of commission, is shipped for metallurgical treatment to Douglas, Arizona. The Pilares mine of the Moctezuma company may be expected to continue turning out about 2,000,000 lb. of copper per month. The smaller mines in the Moctezuma district have not yet recovered from the shock of the crisis, and have produced nothing during the past year, and continue in a state of suspended animation. The Greene-Cananea Co., however, has resumed work under such improved conditions as to convert the old suspicion of failure into a practical certainty of economic success. The long period of suspension was the reverse of being a period of idleness. When work was resumed in September, not only was the old smelting plant rebuilt, upon the original site, but the general design of the furnaces and the methods of furnace-treatment were so improved that on starting, two-thirds of the old production was made with less than one-half the old plant in operation. A more important improvement than the reform of the blast-furnace and converting departments has been the success attending

the reverberatory practice as applied to the smelting of flue-dust and concentrate. Using oil as fuel, half the heat is recovered in the generation of steam, and, by ingeniously feeding highly silicious ore in a steady stream through the roof in contact with the side-walls, it is fettled economically, reducing notably the wear and tear while smelting a highly refractory ore. The bedding system, also designed under the management of Arthur S. Dwight, has been worked out to a practical success. Thus L. D. Ricketts, with the co-operation of Charles F. Shelby, is rescuing a great property from a dangerous position. In Arizona no metallurgical novelties or experiments, not previously under way, have to be recorded.

Steps have recently been taken to revive the Copper Producers Committee, which for some years, under the secretaryship of the late John Stanton, served so useful a purpose. Gradually the old-fashioned principle of secrecy is being weakened, and public companies are being brought to recognize that, if the public endows them with certain corporate rights, they owe to the public certain corporate duties, and, among others, information as to the speed with which they are using up the national resources. To what extent they should divulge their financial as well as their technical operations is a matter upon which opinions necessarily differ; but nearly all have come to admit that their interests are best subserved by taking the public to some extent into their confidence. Prices, for instance, would be more justly regulated by the common sense of the mercantile world than by any combination of manufacturing interests, if the actual facts of production and consumption were known and believed. As it is, the stock of copper, so far as brokers can trace it, is published; but no one supposes that the published figures are absolutely correct, because copper stored by speculators, and the stock of crude material in the hands of the mills, is always a matter of uncertainty.

During the summer before last, had the producers been aware that the demand for copper really fell off in the spring, with the suspicion of a short harvest, they would not have gone on turning it out at maximum speed for some three months longer, during which period the mills were working off the stocks they had undertaken to buy at an exorbitant price. To escape such contingencies a system of contracting ahead would have to be modified, and more perfect harmony of information established between miners, smelters, manufacturers, and the public. This could not be done without the creation of something that would bear a close resemblance to a 'trust' of the most extreme description, and yet, if such a system could be honestly and thoroughly carried out, in all the great branches of trade, it would eliminate those sudden and woefully disastrous shocks which every now and then tend to shatter with earthquake violence the whole industrial system of modern society. If the committee, to which reference has been made, can be re-organized and the result of the accurate information communicated to their statistician be made public, one step at any rate will be

taken toward the consummation of an ideal bureau, which would act as a medium of perfectly reliable information between those producing crude and highly finished articles of commerce and the public that consumes them. If the coming year, therefore, should prove that the motives, whatever they may be, that caused the suspension of the old committee, no longer possess men's minds, and a new committee should be organized, to communicate not only to the trade but likewise to the public the movement of so important an article as copper, and if this be done without any approach to a combination for governing the price, it will mark a distinct impulse in the public mind toward general confidence. It is to be hoped that the large producers on both sides of the Atlantic will co-operate. If 1909 sees a resumption of mutual trust among the producers, may not 1910 see an extension of the same feeling between the producers, manufacturers, and consumers? The tendency of co-operation as at present practised is inevitably leading to state socialism. State socialism means the obliteration of individualism, and all the stimulating influences, good and bad, that are involved in competition. The only brake that can be put upon this undesirable consummation, at least according to the judgment of many men, is by the banishment of secrecy, and therefore of suspicion, between the great corporations and the public.

LONDON MINING MARKET DURING 1908.

By Our London Correspondent.

The year 1908 has been a discouraging one altogether, whether you look at it from the point of view of the mining engineer, shareholder, or promoter. During the last eighteen months, the general industrial depression has caused a slackening in the demand for metals and the consequent fall in price has adversely affected the profits of existing companies and prevented the formation of new ones. The first half of the year was much worse than the second, for during the last few months it has occasionally been possible to place new schemes before the public. For the purposes of this article I have looked up my file of prospectuses of new companies issued during the year; it is a very small file, the smallest that I have collected during the 15 years that I have been keeping records of new companies.

The two most interesting flotations have been the Russian mining enterprises, one the Lena Goldfields and the other the Kyshtim Corporation. The former had been on the stocks for a long time awaiting a suitable time for flotation. It was organized by the Venture Corporation in conjunction with the Consolidated Gold Fields of South Africa, and the Consolidated Mines Selection. This is one of the frozen gravel properties of northeastern Siberia and undoubtedly will prove profitable, but the public subscribed for only a small portion of the issue and the promoters had no easy work to bring the flotation to a success. The other company, the Kyshtim, is a copper company in Perm that promises to do well. Siberia has also won prominence during the year by the re-organization of the Siberian Proprietary

with its subsidiaries, the Orsk and Troitzk. These originally commenced operations under conditions reminiscent of wild-catting, but during the past year the responsibility has been put in the hands of a reliable firm of mining engineers. The operations at the Spassky mine in Akmolinsk have not progressed rapidly of late, owing chiefly to retarding local conditions. The controllers of the company have introduced to the London public recently another copper property not far away, the Atbasar, which I described only a few weeks ago.

There is an inclination among promoters to turn their attention to South America, and if times were only of a more booming kind, no doubt we should hear a good deal about Chile, Peru, and Bolivia. The only companies publicly floated for handling South American enterprises have been the Poderosa, a copper mine in Chile, and the Queen Gold Dredging Co. in Tierra del Fuego. As regards Cornwall, the only two advertised prospectuses were the Boscaswell and the Wheal Fortune, the first of which was a bad failure, and the second only a moderate success. In other ways a good deal of money has been put into Cornwall during the year, notably at Clitters and South Crofty, where additional capital has been subscribed.

North America has been represented by two prospectuses, the Van Roi and the Canada Iron Corporation. The Van Roi was floated by Le Roi No. 2, to acquire the Vancouver silver-lead properties, and the Canada Iron Corporation was formed to consolidate the Canadian Iron & Foundry Co., the Canadian Iron Furnace Co., John McDougall & Co., the Annapolis Iron Co., and the controlling interest of the Londonderry Iron & Mining Company.

During the year, the public has been invited to invest in two companies of technological interest. The Tungsten Metals was formed to treat wolfram ores from Cornwall, and Steelite Explosives was organized to manufacture a new mining explosive. During the last few weeks people interested in oil and bitumen properties on the east coast of Africa have been active and the prospectuses of the Gold Coast Oil & Bitumen Co. and of the British Colonial Petroleum Corporation have been circulated. There is a generally accepted opinion that these oilfields will become of importance before long.

As I have already said, the efforts of the directors to raise additional capital for previously established companies have necessarily been strenuous during the past year. In more palmy days, the new shares of a company that had proved its property could be issued at considerable premiums. In many cases during the year money could only be obtained by issuing convertible debentures of preference shares that carried a right to nearly all the future profits. Notable examples of this were the Zinc Corporation and Stratton's Independence. Another difficulty in connection with the raising of new capital has been the decision in the courts defining the rights of minority shareholders not agreeing to re-construction and assessment. All sorts of devices have had to be invented for circumventing this difficulty.

NEVADA IN 1908.

Written for the MINING AND SCIENTIFIC PRESS
By J. H. G. WOLF.

The past year's mining in Nevada presents a subject of many-sided interest. What is considered Nevada 'mining' by the general public is merely a contracted view of a broader subject. Nevada 'stocks' have depreciated in value within the period in every camp, and save in the cases of a very few companies the depreciation has been from 50 to 500, and even 1000%, while numerous mines have been proved, and are on the road to an early production. This is gratifying to the discriminating investor; it is also a condition fraught with gloom for the mere stock-seller, and the irresponsible promoter.

The chief instrument in producing the change has been the money stringency following the panic of 1907, thus shutting off the supply of funds that sustained ventures of no merit; another factor was the construction of mills in most of the camps, providing means for testing ground that was assumed to be valuable—but was not. Incidentally, in this testing process a few reputations were blasted, and some spectacular figures in Nevada mining were withdrawn. Chas. M. Schwab found that gold and steel would neither amalgamate nor alloy. Mr. Schwab found gold in steel originally, but learned that winning it from mere earth and rock was a more elusive matter. He was unfortunate in interpreting the recommendations of his advisory engineers. Mr. George J. Oliver, also famous in the steel industry, has been more successful, as may be assumed from the results at the Pittsburgh-Silver Peak mine.

Through the agency of mills constructed during the past year the foundations were laid for an assured and continued production of increasing proportions. The cost of mill construction, of complete plants doing fine-grinding and slime-filtering, has remained about \$7000 per stamp. The bulk of the production of the precious metals came from the new camps in the southern part of the State. These will continue to attract money for exploration. In the vast expanse of the southern desert it is hardly reasonable to suppose that all the Tonopahs and Goldfields have been discovered. Development in the new camps has revived activity in the old camps. The improvement in modern methods has resulted in success where nothing could be done before, as at Pioche.

On the economic side, the development of the mining industry made a gratifying advance. Tonopah and Goldfield were given a new outlet to the southwest in the completion of the Tonopah & Tidewater railroad. The Western Pacific railroad construction in Nevada advanced materially, and the eastern part of the State, through White Pine county to Ely, is in railroad communication with Salt Lake, thus giving a shipping outlet for ores from that district. The railroad has also made possible the development of the great copper deposits at Ely, which are among the greatest in the West. In a new schedule just published by the railroads in southern Nevada, the freight rates on all classes of ores are reduced 50% to meet the competition engendered by augmented

milling facilities. The Nevada-California Power Co. has completed its three-step development of Bishop creek, on the eastern slope of the Sierras, and is now prepared to furnish all the power southern Nevada can use for some years to come. The Company has built a duplicate transmission line to Millers, near Tonopah, to ensure uninterrupted service. It has begun an extension of its lines from Millers up Smoky valley to Manhattan and Round Mountain, unaided by guarantees from the mining interests. The length of the transmission line to Round Mountain from Bishop creek will be 142 miles. The labor conditions of the camps have been bettered by the organization of a State police force to maintain order and to prevent rioting in time of labor disputes.

Goldfield is unquestionably the leading district, in population, in production, and in breadth of mining activity. The year has seen no widening of the productive area; the development has, on the contrary, limited it more closely to the zone heretofore proved. This does not augur well for 'outside' properties, but it does not necessarily condemn them; their shares have steadily declined as geological conditions have been deciphered. The shares of the two large companies, the Consolidated and the Florence, are now fairly firm at \$9 and \$4.50, respectively, representing valuations on their outstanding stock of \$32,500,000 and \$5,500,000, respectively. It seems questionable whether they will be able to pay the anticipated 20% dividends on such capitalizations. The mills of these two companies have just begun to drop stamps. The Consolidated mill was designed under the supervision of J. H. Mackenzie, the general manager, by the following staff: J. B. Fleming and G. B. Shipley, mechanical engineers, and F. L. Bosqui, metallurgical engineer. The successive steps of treatment in the new mill are (1) stamping, (2) plate amalgamation, (3) tube-milling, (4) secondary amalgamation, (5) concentrating on Deister slime-tables, (6) agitation in Pachuca tanks, (7) vacuum-filtration, (8) precipitation with zinc dust. Under the direction of the general manager a sub-plant has been installed to treat the concentrate on the ground, using the sulphuric acid process, first neutralizing the base metal content, followed by cyanidation. The various mines of the Consolidated are connected by a standard gauge electric railroad with a mill on Columbia Mtn. On December 26 the new 100-stamp mill, with cyanide annex, was started. The capacity of the plant is estimated at 600 tons per day, and the cost of the plant is estimated at \$760,000. With the railroad, concentrate plant, and water system, the total expenditure will be \$900,000. The mill feed is expected to average \$35 to \$40 per ton, of which 94 to 95% is to be extracted. The total costs of mining, development, and transport are expected to aggregate \$3.25 per ton, while the cost of milling is put at \$2.75, so that the total operating cost is estimated to be \$6 as soon as the mill is in full operation. During 1908 the mining operations on the Consolidated properties have been mainly of an exploratory character, shipments of ore being curtailed. The total profits for the eleven months ending September 30 have amounted to \$552,329.

The Florence mill consists of 20 stamps, with provision for 20 more, and follows in a general way the methods of other successful plants. The mill is not of a unified design, and has been under construction for a year and a half. With the phenomenally rich orebodies opened within the year by the numerous lessees on the company's ground, added to the ore opened in the earlier operations, the Florence should be able to establish a record within a few years. Summing up the Goldfield situation, if the reports in circulation as to the ore reserves be accepted, the highly productive era of the camp should be only dawning, but the future will in all likelihood repeat the history of so many districts, where the rich ore near the surface has been quickly extracted, followed by periods of depression and slow search for additional ore at greater depth and under harder conditions. A mark of the progress of the times was shown in the settlement by arbitration of the dispute between the Jumbo Extension Co. and the Consolidated, and between the Combination Fraction and the Consolidated. This sensible method was also used at Tonopah to settle the contentions of the West End and the MacNamara companies, which had been in the courts for some time. The basis underlying the compromise was the limiting of bounds to vertical planes.

At Tonopah, conditions have been seriously affected by the continued depression of silver. Tonopah is the oldest of the new camps, and is the greatest producer of the white metal in the State. Silver recently dropped to 48 cents, at which price it requires rich ore to make mining profitable. The shares of the Tonopah companies have dropped to depressing figures, despite the better facilities that now exist for milling the ore. The limits of the producing area have been known for some years, and the leading mines have but lately resumed exploratory work for additional ore below the dacite intrusion. The Tonopah Mining Co.'s 100-stamp mill at Millers, 13 miles below the town, has been reducing 13,000 tons of ore monthly, having a reported average assay-value of \$21 per ton. The 60-stamp mill of the Belmont, also at Millers, has extended its sphere of operation to custom work for other Tonopah mines. The Montana mine has built a 40-stamp mill in the camp; it is doing excellent work on a complex silver-sulphide ore, using the following treatment process: (1) stamping in solution, (2) primary concentration upon Wilfley tables, (3) tube-milling, (4) secondary concentration upon Frue vanners, (5) agitation in Hendryx agitators, (6) vacuum-filtration, (7) precipitation on zinc dust. An extraction of 90% is reported. The monthly ore output of the Tonopah mines has averaged about 24,500 tons.

The Bullfrog district is the railroad centre of southern Nevada. Cheapened transportation, with electric power, has hastened mill construction: half a dozen plants have been erected. The ores are proving lower in grade than was expected, compelling some of the mills to shut down. Gold is the predominant metal in the ores. The Montgomery-Shoshone, the largest mine in the district, is opened to 600 ft., and is producing \$40,000 to \$50,000 monthly.

Manhattan has made progress toward bettering its

condition during the year. Four mills have been erected, and do custom work; one is equipped for fine grinding and slime-filtration. The mills await the advent of electric power to cheapen working costs. The mines generally are without capital to do deeper work, hence the leasing system prevails. Litigation over title has tied up much property that is believed to be valuable, especially at the east end of the district; consolidation of holdings would materially improve the situation and attract capital to make the better prospects into mines. Manhattan stocks have suffered much in the general depression. Favorable placer possibilities now appear in the main gulch below the camp.

Round Mountain, yielding gold ore that is exceedingly easy to treat, has made a record in production from its four or five small mills, greatly enhancing the output of Nye county. The camp has held its own through panics and through stress of adverse conditions, such as the lack of cheap power and transportation. Meanwhile the principal mine has been proved to a depth of 700 ft. The hydraulicking operations, following the good results obtained by dry-washing the year before, were hampered by lack of water. The small seams of gold, so abundant in the rhyolite country along the mineral zone, have created excellent possibilities for placers.

The Blair mine, of early days at Silver Peak, situated 30 miles west of Tonopah, was taken over by a Pittsburg syndicate, which has developed it into a mine of importance. For the quick and economical development of the property, a standard gauge railroad, 18 miles long, was first built to connect the mine with the Tonopah & Goldfield railroad. A mill of 100 stamps was erected and put in operation in April; the reported production has been \$750,000 to date. The treatment used is stamping, amalgamation, followed by cyanidation, leaching the sand, and treating the slime in the Merrill filter, of the type used at the Homestake mill in South Dakota. The mine, embracing 8000 ft. of lode which outcrops along the Silver Peak range near its crest, is at an elevation of about 2000 ft. above the town and the mill, with which it is connected by an aerial tramway $2\frac{1}{2}$ miles long.

Fairview and Wonder have been quiet during the past year. The Nevada Hills, the producing mine of the former district, has confined its operations principally to development work, though some ore has been shipped. Lack of transportation and cheap power are obstacles here as well as at Wonder. These camps yield chiefly silver, and the price of that metal has been a deterrent upon operations. The Nevada Wonder has been developed to 500 ft., and the ores are being tested on a large scale to determine the best methods of treatment. A mill will probably be built during the ensuing year.

Rawhide is the newest of the Nevada camps to bid for favor and support. It is situated about 100 miles southeast of Reno. A mineral showing of promise is found in eruptive rhyolite and andesite, outcropping on the low summit of the range dividing Gabbs valley from Walker lake. In April, at the height of the boom, 7500 people found shelter there;

the fire in September swept away the business centre and caused an exodus. The camp has been opened by the leasing system, to the exclusion of company operations, and the work done to date gives promise of proving the worth of a number of mines. The shipment of ore has helped materially to pay for further exploration. The ores contain both gold and silver, the former in the rhyolite on McLeod hill, while gold and silver are found together in the silicified breccias forming ore-zones in the later rocks. No reduction works of importance have been erected; a railroad is projected, and the grading partly done, to connect Rawhide with the Southern Pacific tracks at Walker lake, where the conditions are favorable for cheap milling. Barring the trials that beset all new camps from the evil effects of misrepresentation in the effort to sell stocks, Rawhide has a favorable chance of winning an assured position.

The copper district of Yerington, in Lyon county, has been the scene of energetic development, in the course of which shipping ore has been steadily marketed. The projected smelter has not been built.

The promise of Ely, the camp in the eastern part of the State which was explored in the early days for gold, has been realized in the great work carried to completion by the Guggenheims. Twenty million tons of copper ore available, assaying about 2%, have been proved, and a reduction plant of large capacity is now in operation in the Steptoe valley, 22 miles distant. The first mill-unit of 1500 tons was started in July. With practically unlimited capital and the best engineering and metallurgical talent in the country at the command of the enterprise, it stands today as Nevada's greatest mining enterprise.

The review of mining in Nevada for the year is not complete without referring to the Comstock and Virginia City. The present yield from that famous locality may not be important, but it is significant of energies not wholly decadent, and also of what may yet come from the famous Lode if success follows the efforts of those seeking to rehabilitate these famous mines. The record of the Comstock's production of the precious metals in the past is enormous—greater than the present annual output of all the mining districts of the Western States. The production for the year will be roughly \$750,000, taken principally from the Ophir, and the Chollar, and the Yellow Jacket croppings, which, while small compared with past yields of \$2,000,000 per month when the mines were in bonanza, is still important. It does not, however, present a favorable appearance, in view of the \$800,000 collected annually in assessments. The outcry against the Comstocks is not because of the mere fact of levying and collecting assessments, but is against the want of faith in the disposition of the money, and the small amount of mining actually performed on many of the properties. With but five shafts remaining open (that are not caved) along 2½ miles of the Lode, down to the deeper workings below the Sutro Tunnel, there is little hope of an early general resumption of mining on the deep levels, where commercial ore is most likely to be found. One of the above shafts is filled with water to the Sutro Tunnel level, and in a second shaft the water is about

300 ft. below that level. The sum of all the assessments collected in a year will not suffice to reclaim a single lost shaft, nor restore to good condition the Sutro Tunnel with its branches, upon the maintenance of which the possibility of deep mining depends. A favorable element in the work of rehabilitation is the broad treatment given the difficult problems by the engineers in charge. The Lode with its 200 miles of mine workings, much of which, however, has collapsed, must be treated as a whole to accomplish anything effective. The works planned with the machinery already installed are of such character and capacity as will suffice for almost any situation that may arise on the resumption of deep mining. The Reidler pumps, at the C. & C. shaft, having a capacity of 4500 gal. per min., and the Deane pumps of 3300 gal. per min., at the Ward shaft, working against a 1500-ft. head, represent the latest and best installations of their kind. Both are electrically driven. One of the Deane pumps is now set temporarily on the 2475-ft. level, but both are intended to be placed permanently on the 3100-ft. level. Sinking from the 2550-ft. level is ready to be resumed at this shaft, but with a pressure of 400 lb. per square inch against the restraining works holding back the waters on the Gold Hill side. The status on the Comstock might be disturbed beyond the mere drowning of the pumps if the Gold Hill flood were let down upon them. The present dependence for ore is upon the north end. The Con. Virginia opened during the summer a lens of ore on the 2150-ft. level, but it has not afforded a large tonnage. The Ophir stopes from the 2000 to the 2200-ft. levels continue to yield good ore at the rate of \$10,000 to \$12,000 per week. The character of the ore, and the ratio of 45 to 55 between the gold and the silver continues as in the upper levels. Ore of commercial grade has not yet been found on the 2300-ft. level. In the Mexican, ore has been found in driving northeast from the north line of the Ophir on the 2200-ft. level. With the changing character of the weekly assay-report it may be assumed that the drift is being run on the apex of a lens. From the position of the ore in neighboring ground, there is warrant for the belief that an important orebody will be found in the vicinity. This is the one mine on the north end that has not yet produced ore. Reform the Comstock? It is an idle and an unnecessary suggestion. It is for the stockholders—the mine owners—to combine their properties for economical working, to support the measures laid out for rehabilitation, wherein lies the possibility for an early resumption of mining on a scale at all comparable with the expectations which its past history has fostered.

The immediate hope of Nevada lies in several small gold camps, any one of which may develop to greatness. At Seven Troughs, two or three mills have started; Chafey looks cheerful, although the ore is low-grade. Old camps like Pioche, Searchlight, and Silver City are being resuscitated. Aside from these is the outlook for a great revival of lead mining in the vicinity of Las Vegas, and the development of new impregnated copper deposits like that at Ely is predicted.

ALASKA AND THE YUKON.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The history of gold mining in the extreme north-western corner of the American continent divides into two periods: one characterized by the discoveries near Juneau, with the development of the Treadwell lode, and the other by the uncovering of rich placers at Dawson, Nome, and Fairbanks. The first period started with the finds made by Juneau and Harris on Gold creek, in 1880; the second and more important series of events began with George Carmack's discovery on Bonanza creek in 1897. Between these two dates some desultory prospecting was done along the coast, and a little placer mining at Forty-Mile, Circle, and elsewhere in the watershed of the Yukon. During this interval the Alaska-Treadwell gave fame to the region, encouraging the hope that other large ore deposits might be discovered. Indeed, some rich mines were found on Berners Bay and elsewhere in the Juneau district, but the vast interior of the country, now the scene of such productive activity, remained unknown and disregarded.

Since 1897 the alluvial deposits of the Yukon and Alaska have yielded fully \$200,000,000. This has been extracted at a profit unusual in mining, as it was derived from superficial concentrations of gold-bearing gravel, comparable in their richness to the deposits that excited the world in the early days of California and Victoria. The feverish production of gold from the Klondike and Tanana valleys, and from the beaches of the Seward Peninsula, lasted for two or three years. Since then there has been a decline in the yield. The decrease has led to the query whether, after all, this phase of mining must not necessarily be short-lived, being dependent upon small and shallow deposits of extraordinary richness, rather than immense accumulations of gold-bearing material such as have afforded the basis for long-continued operations in older mining districts. I confess that when I started last June to make a journey of observation through the North, it was with the expectation of finding evidence of an ephemeral industry. Men who ought to have been fairly well informed had told me that the placers were showing signs of exhaustion and that for an assured future Alaska must look to her copper and coal resources. That view, moreover, accorded with experience elsewhere. But it was wrong.

Leaving San Francisco, the traveler goes by sea for 1700 miles before he reaches Skagway; there the railroad of the White Pass & Yukon Route takes him over the coast range to White Horse, a distance of 112 miles; then he descends on the upper waters of

the Yukon river to Dawson, another 450 miles. From Dawson the journey down the Yukon, now a lordly river, is 1600 miles to Bering Sea, with 110 miles more to Nome. From Nome to San Francisco direct the voyage is 2730 miles. Thus, after crossing the coast range by the White Pass, at an altitude of 2880 ft. above tide-water, and only 20 miles distant from the wharf, the traveler descends the Yukon for 2144 miles before he reaches the sea again. These figures are cited for the purpose of emphasizing the extent of the region. The District of Alaska covers 580,000 square miles, and the Yukon Territory, 200,000. Until some notion of the immensity of the area is obtained, it is impossible to realize the difficulties of transport, the relative insignificance of the population, and the limitless possibilities for further discovery.

Dawson and the Klondike.

Dawson is the first important mining centre reached by the traveler. It is true that there are some promising copper mines at White Horse, and

Map Showing Relative Size of Alaska.

After U. S. Geological Survey.

on the Stewart, White, and other tributaries of the Yukon work is in progress, but as I purpose making a broad review of the country and of its future prospects, we shall land mentally at the mouth of the Klondike, where Dawson spreads itself along the river front. It is not necessary to recite the tale of first discovery, the stampede that amazed the world, nor the evolution of mining methods, each of which would form matter for an interesting story. Let us see Dawson as it is today. Until three years ago the mining operations of individuals, syndicates, and small companies sufficed to exploit the rich claims that had been located on the various creeks flowing into the Indian river and the Klondike, both of which are tributaries of the Yukon. The creeks are thus divisible into two principal groups: (1) those draining northward into the Klondike river, including Bonanza, Hunker, and Eldorado, and (2) those, on the south side of the Dome ridge, flowing into the Indian river, such as Dominion, Sulphur, and Quartz. While the second group has yielded a good deal of

gold (about \$25,000,000), the bulk of the output (or \$100,000,000) has been derived from the first group. At the present time mining is proceeding in a desultory manner on the south side of the Dome, but an enlargement of the scale of operations is likely next season. The main centre of activity is on Bonanza and Hunker creeks, where a large consolidation of property has been effected. After individual mining in a sporadic manner had proved the richness of the creek deposits and had led to the discovery of important bench gravels, an English promoter named A. N. C. Treadgold succeeded, by persistence and obstinate good sense, in obtaining options on enough claims to form the nucleus for a big mining enterprise on the Klondike watershed. He succeeded in enlisting the financial participation of the Guggenheims and the technical assistance of the engineers

enriching Bonanza creek at that point, but cutting a hole in the bench gravel. The engineers estimate that they have 47,000,000 cubic yards in the White Channel, and the yield is estimated at 32 cents per yard. Actual tests have given returns ranging from 30 cents to \$2.30 per cubic yard. The deposit is easy to disintegrate when once thawed; when hydraulicking begins, with ample water under heavy pressure, a duty of 5 cu. yd. per miner's inch may be expected. In order to obtain room for the tailing discharged from these hillside operations, it was necessary to control the creek claims. This has been done; and as they become worked out, by dredging and other methods, the tailing from the White Channel will be discharged upon them, until the hillsides and valleys are a gray desolation, on which the Arctic moss will eventually spread a protecting cover, as before the irruption of man into this northern wilderness.

The Yukon Gold Co. now controls the ground made famous by the Klondike rush, and is ready to conduct operations on a large scale. About \$11,000,000 has been spent in equipment and purchase of ground during the last three seasons; an electric power-plant, a 70-mile ditch system, seven dredges, sundry reservoirs, several pipe-lines, and all other requirements for alluvial mining in a systematic manner have been completed. Next year will see the beginning of large operations, which are certain to be productive and profitable. This important enterprise has suffered from being associated with a disreputable trickster at Boston, but it is in the hands of clever people, and the technical direction has been given to professional men of recognized ability, so that there is every prospect of results of far-reaching importance. The failure of the Yukon Gold Co. would be a dis-

employed by that enterprising family. Thus the Yukon Gold Co. was created.

In the creek-beds of the narrow valleys are fluvial deposits of extraordinary richness. Most of the claims have been worked already, and the tailing from the first operations is rich enough to be re-worked. But some of the ground is virgin, and will yield as much as \$2 per cubic yard through a depth of 15 to 20 ft. In addition to these creek deposits, there are bench gravels of Pliocene age. These constitute the celebrated White Channel, an older deposit, through which the present valley has been eroded, with enrichment of the creeks by concentration of the gold from that older deposit. The bed-rock of this White Channel is 195 ft. above the surface of Bonanza creek; the greatest vertical thickness of the deposit is 110 ft., and the biggest horizontal width of gravel is 1200 ft. Several of the hillsides expose gravel-beds 800 ft. wide for a vertical height of 40 to 45 ft. The longest face on any one hill is 4000 ft. Each lateral gully and tributary entering Bonanza has cut into the White Channel,

aster to the mining industry of the North; the success of it will stimulate other operations on a large scale. Success seems assured.

While the Yukon Gold Co.'s work is much the most important undertaking in the district tributary to Dawson, it must not be supposed that these operations include all the local activity. On the south side of the Dome, and even on the northern watershed, so largely dominated by the Guggenheim holdings, the alluvial mines are producing gold and they will continue to do so, but it must be confessed that the possession of water-power and the control of the major portion of the room available for tailing will give the Yukon Gold Co. an opportunity to acquire most of the rich ground on the north side of the Dome. This has annoyed, and will further annoy, many good people who dislike the too complete dominance of a single concern. However, it will enable many claim-holders to dispose of their property at a good profit, and it will distribute money among men who will thus become equipped for further exploration in the surrounding wilderness. Every large

mining company acts as a feeder for local enterprise by affording the capital needed by the individual operator, whether that capital take the form of large sums received for claims, or wages paid to workmen, or money transferred to local merchants in exchange for supplies.

Outside of the Dawson district, there is activity in dredging on the Stewart and the Forty-Mile rivers. Some of the dredges have done well during the past season and there is encouragement for an extension of this kind of mining; but such favorable comment must be accompanied by a warning lest it lead to misunderstanding. The old blunders, of using machines of light construction, of attacking ground that is partly frozen, of insufficient drill-testing before dredging, and inadequate equipment afterward, are repeated, needlessly and scandalously. There

successfully in the washing apparatus on the dredge. Another feature of the work done during recent years has been the discovery that along many streams the channel is not frozen, so that dredging can proceed with but little hindrance. This has been the experience in the Klondike valley and on the lower reaches of the Forty-Mile river. It must be remembered that all the early alluvial mining was done in frozen ground, for thawed gravel meant pumping, timbering, and other expenditures anxiously avoided by the Alaskan or Yukoner. Owing to the difficulty of testing thawed ground in the ordinary way by shaft-sinking, the exploration of the deposits most suitable for dredging was delayed until churn-drills were employed intelligently. Drilling is now in progress at many points and a large amount of systematic information is being collected. This will

Map of Alaska.
After U. S. Geological Survey, with additions.

is no excuse for these childish mistakes, the experience now available should obviate the repetition of them, and all who speculate in this form of mining should take pains to apply the lessons of the past for the better illumination of the future. One lesson learned during the last two or three seasons is the hopelessness of trying to dredge in frozen ground—that way lies destruction of the dredge and disaster to the enterprise. On the other hand, the work done by the engineers of the Yukon Gold Co. has proved that thawing with steam is not as costly as was supposed; in ground 20 to 25 ft. deep the expense is 15 to 20c. per yard, and by stripping the overburden of moss and ‘muck’ this figure can be reduced one-half, so that the method is vastly cheaper than blind butting into a solid mass of frozen gravel, which, even if it be dug by the buckets, cannot be treated

prepare the way for the intelligent application of dredging, elevating, or any other form of placer mining deemed suitable to local conditions.

Fairbanks and the Tanana Valley.

The three great mining centres of the North are Dawson, Fairbanks, and Nome; they are so situated as to serve as distributing points for separate regions. Dawson, being just east of the American-Canadian boundary, is a point of departure for the miners in the Yukon districts on the one side and also for Circle, Eagle, and other camps that are in Alaska but near the boundary and down-stream from Dawson. Fairbanks is on the Tanana river, at a point 275 miles above its confluence with the Yukon; this town is the supply point for the entire Tanana valley, and also for the prospectors going up the tribu-

tary streams. Being in the heart of interior Alaska, Fairbanks is steadily gaining in importance; someday it will be a division point on a railroad from the Lynn Canal to Nome—at least, that is what some of its intelligently optimistic citizens assert. Nome, of course, is the port of entry for the Seward Peninsula and the extreme northwestern corner of Alaska, as well as for the Siberian coast opposite.

The first discoveries of gold in the Tanana region were made in 1902. In 1905 the output of gold was \$3,750,000; in 1907 it was \$7,500,000; and in 1908 it is estimated to have been \$9,000,000.

The region tributary to Fairbanks consists of a number of contiguous districts traversed by different creeks possessing alluvial deposits varying greatly in dimensions, depth, and richness. For the most part the gold-bearing channels occupy the beds of open valleys sunk about a thousand feet below the ridges separating them. The gradient is slight, averaging about 100 ft. per mile.

The first discovery was made on Pedro creek, a tributary of Gold Stream. During the last two years this gold-bearing channel has been traced for eight miles down Gold Stream and up the lateral gulches. Cleary creek was the scene of the first big finds and yielded fortunes to many operators; since then the channel has been followed into the Chatanika valley, where deeper mining, by 'drifting,' is required. Similarly, Esther, Dome, Vault, Treasure, and Fairbanks are the names of small creeks flowing along valleys in which gold mining has been undertaken, with varying success. Esther creek in 1908 was one of the best. Thus the name of Fairbanks represents a goldfield covering fully 200 square miles and a score of known alluvial channels containing gold in profitable proportion.

The bedrock is schist and quartzite-schist; it is usually soft, shattered, and easily mined. The gold lies within the crevices of the bedrock and in the bottom layer of the fluvial deposit. The 'gravel' consists of angular and sub-angular fragments of the prevailing country rock. Most of the gold that is extracted comes from the sediment lying upon the bedrock and from the uppermost portion of that bedrock, at least two feet of it being removed and washed in the sluice-boxes. A yield of \$1 per square foot of bedrock uncovered is a fair return for a 'drift' mine that is 14 to 15 ft. deep. Profitable mining has been done, by 'drifting,' as deeply as 150 ft. On No. 4 and No. 5 Below on El Dorado, for example, the pay-gravel is 80 to 90 ft. wide. The portion removed includes 4 ft. of alluvium and 2 ft. of bedrock. I saw pieces of gold weighing over two ounces that had been taken from this ground in July. The local unit is the gravel lying upon a square foot of bedrock. A fair return is \$1.50 per square foot, at 25 to 60 ft. deep; the thickness of material extracted is usually 6 ft. and a pay-channel 80 to 100 ft. wide is considered excellent. The gold is coarse, sometimes very coarse. On No. 5 Little El Dorado on August 3, 1908, the clean-up yielded 296 oz. gold, not one-half of which would go through a sieve having apertures of $\frac{3}{16}$ inch. The largest nugget weighed $10\frac{1}{2}$ oz. Naturally, the cheapest

mining, and therefore the most successful, is done where the ground is shallow and completely frozen. In the upper valley of Cleary, for example, at No. 1 Below, the bedrock is found at a depth of 18 ft. A vertical section shows 2 ft. of moss, 10 ft. of overburden, 5 to 8 ft. of pay-gravel. Since 3 ft. of bedrock is mined, the total thickness of profitable material is 7 to 12 ft. This ground is stripped with scrapers and then removed by self-dumping buckets. The Discovery claim, a short distance farther up the valley of Cleary, has yielded over \$1,000,000 in four seasons and the bench claim adjoining has given \$500,000. On the latter J. C. Smith and his associates took out \$20,000 in 32 hours. The remnant of ground remaining is 33 ft. deep and is worked by 'drifting.' Thawing with steam-points at night is followed by pick-and-shovel work in the daytime, aided by a self-dumping bucket, which carries the gold-bearing stuff to the sluice-boxes.

Mining has been confined mainly to 'drifting,' that is, sinking a shaft in the frozen ground to bedrock and then extending galleries underground on top of bedrock. Only recently has there been any attempt to employ the open-cut method systematically. As a rule the bedrock is too deep to permit of open-cutting. Dredging has not been attempted, as yet.

Distance down-stream does not necessarily mean additional depth to bedrock; there are many curious changes of level. A shaft in the Chatanika valley, below the confluence of Vault creek, went down 315 ft. in frozen ground before bedrock was reached. Twenty miles farther the valley narrows and bedrock outcrops in the bed of the stream. For miles the bedrock is then only 8 to 10 ft. deep. On Gold Stream, near the confluence with Moose creek, the depth to bedrock is 35 ft., while above, at the mouth of El Dorado, a shaft was sunk 186 ft. to bedrock. The existence of small lakes, and the low divides between some of the valleys, suggest that erosion and elevation have made important changes in the hydrography of the region.

On several creeks the bedrock is so deep as to tax the miner severely. The bedrock of Dome creek is 60 to 170 ft. deep; on Vault the shallowest mines are 100 to 175 ft. deep; on Treasure, the depth is 180 ft. Even rich ground is unprofitable under such conditions. On Esther creek No. 6 Above shows bedrock at 22 ft., No. 3 Below gets into bedrock at 45 ft., and No. 8 Below at 92 ft.; but the gradient is not regular.

The important fact remains that there is much ground that is 40 ft. deep or less: on Cleary, from 3 Above to 4 Below; on Fairbanks, as far as 10 Below; on Pedro, all the way from Twin creek to 10 Below, where it joins Gold Stream; on Gold Stream as far as 9 Below. More ground of this character is likely to be found when the region is carefully prospected. There are scores of creeks on which no hole has been sunk to bedrock, because the ground is not wholly frozen and is therefore not adapted to mining through shafts. Such tracts have not been tested even by drilling, as yet. A ride on horseback along the dividing ranges in late summer, when such an expedition is practicable by reason of the drying

of the mossy covering of the ground, will suggest to any observant engineer that there remains a wide stretch of untried possibilities within the heart of this almost untrodden wilderness. According to Lucien S. Robe, a resident engineer, there is a spa-

region is badly situated. The creeks drain no lofty mountain range; their watersheds are low hills, on which the snow does not rest in summer. The catchment areas are small. During the summer the creeks are fed by ground-water, derived from the melting

On Dome Creek, Yukon.

cious region 60 to 125 miles south of Fairbanks where dredgeable gravel 15 to 40 ft. deep is spread; this gravel runs \$3 "per shovel," that is, the quan-

of tundra ice. The run-off per square mile of drainage-area was unusually low this year, from 25 to 35% lower than in 1907. Any shower is at once

Rudimentary Alluvial Mining in Alaska. This Method is Known as 'Shoveling In.'

Photograph loaned by U. S. Geological Survey.

tity a man with a No. 2 shovel can move in a shift of 10 hours—about 6 to 7 cu. yd. Such statements are, at least, suggestive. There is a splendid scope for intelligent prospecting in behalf of experienced operators.

From a hydrographic standpoint, the Tanana

felt in the increased volume of the creeks, because the tundra is in a saturated condition from the thawing of the sub-soil ice. The effect of a shower is temporary. There is no natural storage: the sparse growth of trees is unfavorable to economy of snow or rain, no high mountains furnish resting places

for snow, and the low gradient of the valleys prevents any hydraulic head being available for mining operations. Under such conditions hydraulic mining is impracticable, and even the construction of long ditches is not to be encouraged. In order to obtain head it is necessary to go up-stream; in going up-stream the flow available decreases rapidly, because the supply comes from ground-water, not from snow-fields at the source. Transmission of power as electricity is practicable, the application of the dredge and the mechanical elevator is worthy of investigation, and the conservation of water is imperative. I shall return to this part of the subject again; the facts to hand emphasize the richness of the Fairbanks region, and the wide area of fluvial deposits containing gold. If situated in a country less large and less remote than Alaska, Fairbanks would be recognized as one of the great goldfields of the world.

Nome and the Coastal Plain.

Descending the Yukon we reach Bering Sea and cross Norton sound to the southern shore of the Seward Peninsula, where Nome looks westward toward Asia. The first mining was done on Ophir creek in 1897 and the first beach discovery was made in June 1899. Gold had been found by white men as early as 1888, but no mining resulted. The rush to Nome was due to the finding of gold in the sea-beach during the summer of 1899; the following year saw the stampede. The output of gold from the Seward Peninsula during the ten years since 1898 is estimated at \$50,000,000. The maximum was reached in 1906, when the Third Beach proved so productive. Of the total output fully \$22,000,000 has come from the sea-beaches, present and ancient. In 1908 production suffered from a scanty water-supply, the precipitation being half the normal, so that only \$5,000,000 was extracted.

This is an enormous tract of mining country; the Peninsula includes 20,000 square miles, the major portion of which is mineral-bearing. For the purpose of description the gold-bearing areas may be divided into creeks and beaches. No vein mining of any consequence is being done, the one important mine (the Big Hurrah) having closed down. On the creeks the methods of mining and the conditions of gold occurrence resemble other parts of Alaska, except that limestone and lime-shale often constitute the bedrock, alongside the schist. This harder bedrock modifies the concentration of the gold and influences the cost of mining. On Anvil, Glacier, Dexter, Ophir, and other streams extraordinarily rich placer deposits have been found and exploited successfully. The rudimentary methods of the first prospectors have been followed by open-cutting, the use of the hydraulic elevator, and finally by dredging. An enlargement of the water-supply has been ensured by the construction of several long ditch-systems, such as the Miocene, Seward, Penny, Pioneer, Cedric, Topkok, and Paragon, all of which are fed from a watershed in the high mountains in the central portion of the Peninsula. By aid of this water the stream and bench deposits of gravel have

been mined successfully, if extravagantly. The yield has discouraged economy and it is only lately that technical efficiency and businesslike administration have replaced the flamboyant ways of the boom period.

From the fluvial deposits along the bottom of the gold-bearing streams of the Peninsula there will be much gold extracted, even by re-working ground already exploited by the hasty methods of the first operators, but the chief interest centres on the possibility of mining the coastal plain behind the town of Nome. To understand the character of this deposit, it will be necessary to outline the story of the beaches.

Gold was found in the sand of the shore bordering Bering Sea in 1899 and fortunes were dug by mere washing of the detritus that the tides had concentrated into a fringe stretching for many miles between Cape Nome and Point Rodney. In 1902 gold was found on the edge of the tundra back of the beach and the continuity of a rich deposit of similarly concentrated particles of gold, garnet, and magnetite was proved. This was traced across the

The Beaches of Nome.

tundra for 9 miles in a line nearly parallel to the present shore and was called the Second Beach. A low escarpment covered by the tundra indicates the origin of the deposit, which was worked profitably in a number of mines for a distance of 2 to 3 miles. The gold lay on a false bottom of clay 37 ft. above present tide-water. This stimulated further search, which was now aided by the preliminary reports of the U. S. Geological Survey. In the fall of 1904 the Third Beach was discovered, through the accident of a shaft being sunk in a creek where the beach deposit crossed. This Third Beach lay on a false bottom at 70 ft. above tide-water and an average of 45 to 60 ft. below the present surface. It followed a flat crescent, the horns of which were near Cape Nome and Point Rodney, and thus it marked the line of a former shore. The distance from the present beach to the Third Beach through Nome is 3 miles and the rise is 68 ft. Subsequently an intermediate beach was found, about $1\frac{1}{2}$ miles inland, and 22 ft. above sea-level, but on bedrock. Other deposits of the same nature, but less continuous, have been found. Thus it has been demonstrated that the

coastal plain stretching east and west from the town of Nome is underlain with a series of old marine concentrations of gold-bearing gravel. Of these, the Third Beach has yielded about \$15,000,000 and has contained some wonderfully rich spots. From a littoral fringe (now 50 ft. underground) 25 ft. wide as much as \$3000 per running foot has been taken for a distance of 110 ft. While the ground was extracted for a depth of 3 ft., the rich pay consisted usually of a couple of inches of the bottom and an inch of the overlying sediment. These beaches cross the present creek-valleys and gullies, cutting across the tundra from the coast range to the sea. Thus Hastings, Dry, Bourbon, and Anvil creeks have been mined, and also the Nome, Snake, and Penny rivers, in all of which placer deposits have been formed by the concentration of gold from the hills to the north and by the concentration of the gravel constituting the coastal plain itself. The question then arises whether the whole coastal plain is not a workable gold-bearing alluvial flat.

The coastal plain is an immense talus spread along the shore of Bering Sea and extended southward as the land has been slowly elevated. Of this geological fact there is ample proof. The source of the tundra gold is the mineralized schist of the foothills that rise above the flats at a distance ranging from 3 to 3½ miles due north of Nome. This is at the centre of the sweeping curve made by the old coast between Cape Nome and Point Romney. The creeks that cross this plain on their way to the sea are richer than the mass of the deposit simply because the amount of gravel has been diminished one-third, while the gold from the third that has been washed into the sea has settled to bedrock. Owing to the clean character of the overburden, the gold has settled, until finally a layer of clay has arrested further descent. Thus it is found on a false bottom at some distance above bedrock. Vertical sections of the deposit have been obtained from bore-holes and shafts. While most of the gold is concentrated toward the bottom, there are enrichments at 10 ft. and at 20 ft., as well as at other horizons. In the creeks a return of 50 to 70 cents for a thickness of

35 to 40 ft. is recorded by numerous drill-holes; on the tundra the depth is 40 to 60 ft. and the sampling indicates a more variable yield, from 25 to 40 cents per cubic yard. Even in the deepest holes the particles of gold are sufficiently numerous to suggest that the whole mass might be worth exploiting.

The richest portion of this coastal plain is from Nome river to Snake river, a distance of 9 miles. Here the maximum width is 3½ miles. At a rough estimate there is here 25 square miles of gold-bearing territory. The depth may be averaged at 50 ft. I shall not make any calculation as to the millions of cubic yards of material existing within these limits, because any of my readers can perform this

simple arithmetical exercise for themselves; moreover, it is not likely that the entire area is equally gold-bearing, nor indeed is all of it likely to be rich enough for profitable mining operations. My purpose is simply to draw attention to a most important stretch of gold-bearing country, known to be rich enough to invite systematic prospecting. The facts available at this time warrant the expenditure of money in drilling and in other methods of testing; the information at hand as yet does not justify the launching of big schemes of operation.

Any plans to exploit this most interesting deposit of gold-bearing detritus must have reference to the flat slope of

Vegetables Grown in the Summer of 1908 at Fairbanks, Alaska, Latitude 64° 51' North.

the bedrock, the frozen condition of portions of the deposit, the thawed condition of other portions, the covering of moss, and the disposal of tailing. The tundra can be ground-sluiced for the removal of the covering of moss for a cost of about \$2500 per acre. If the ground is then drained and the warm summer rain allowed to percolate through the exposed gravel, it may be possible to thaw without using steam-points. In any event, here is a problem and a possibility well worthy of the attention of technical skill and speculative energy.

Mining in the North is hindered by the high cost of transport. The freight rate to Fairbanks from Seattle or San Francisco ranges from \$75 to \$150 per ton by the two companies that control the river traffic. To Nome the rate is \$12, one-third of which is charged for lighterage. In consequence of the high

cost of transport, the wages paid workmen range from \$4 to \$6 per day, plus board, which costs from \$1.50 to \$3, according to locality. The operators complain of the high wages and the workmen in the mines complain of the small margin left after paying for the necessities of life, and the cost of getting into and out of the country. Most of the men migrate at the end of the summer season. This entails economic waste. At Nome it is not so bad, but at Fairbanks the coming and going consume an amount of money and time that is a severe tax on the industry, which pays it indirectly. The cost of mining at Nome is sure to be diminished shortly, for both labor and supplies are certain to be cheapened by the facility of ocean transport, but at Fairbanks no marked decrease is likely so long as the two transportation companies unite in controlling rates and maintaining them at a prohibitive figure. A railroad from Lynn Canal to Fairbanks would change the entire economic aspect of the interior of Alaska.

Lack of water is another drawback. The interior of Alaska is an arid region. Most people are so accustomed to thinking of the country as covered with snow and ice that they do not realize the dryness of the climate. Southeastern Alaska, to which most tourists go, is abnormally wet, the precipitation at Juneau being from 95 to 100 in. per year. In 14 years the rainfall at Juneau averaged 93.7 in. At Fairbanks the rainfall in 1906 was 10.63 in. At Tanana in four years it averaged 15.45 in.; and in 1907, 14.10 in. At St. Michael the average is between 16 and 20 in. At Nome in 1907 it was 16.69 in., and in the first six months of 1908 it was only 3.49. No wonder the placer miners are short of water, or that it sells for \$1 per miner's inch per day. And yet the Alaskan often uses his water wastefully, employing it in hydraulic operations of low efficiency. In many cases it would be more economical to transform the energy of the stream into electricity and transfer this power along a copper wire for use in machinery, such as the dredge or the mechanical elevator. In some cases power can be obtained from the ditches, at their upper end, without severe curtailment of the pressure available at the mine; under such conditions the water, after use on a wheel, could be returned to a lower ditch, undiminished in volume. In a region presenting unusual difficulties to the building and maintenance of ditches, it is cheaper to transmit power as electricity. A wire can be stretched farther and more easily than a ditch can be dug or a pipe laid. The small trees growing in the interior of Alaska will usually provide sufficient poles close to the place where they are to be erected and the climatic conditions are favorable to the maintenance of such a pole line. The average cost of an electrical transmission line conducting 30,000 volts is \$1000 per mile, while the average cost of a ditch able to deliver 5000 miner's inches (7500 cu. ft. per min.) of water is \$20,000 per mile. At Nome oil is delivered for \$2.75 per bbl. By burning this comparatively cheap fuel, transmitting the power to scrapers, mechanical elevators, and dredges, while using the water for washing the gravel, an economic operation is practicable.

The purpose of mining is to make a profit, which is measured by the difference between yield and cost. It matters but little whether the cost is high if the yield be proportionately large. The tendency is to look most favorably on large low-grade deposits, operated at a small cost and returning a steady income; they are preferred to rich deposits because their persistence as ore deposits ensures the life of the industrial undertakings for which they afford a basis. Men have learned that rich mines are short-lived, usually; therefore they anticipate the brevity of an enterprise founded on bonanza ore, until actual proof of big reserves is forthcoming. This is a sensible attitude, for it is justified by experience. On the other hand, low costs do not always spell success, nor do high costs necessarily entail failure. It may be more profitable to use 'steam-points' and dredge at a total cost of 25 cents per cubic yard in one locality than to dredge easy ground for 5 cents per yard in another place; everything depends upon the amount of gold extracted as a result of these operations; a yield of 80 cents in the one case gives a profit of 55 cents, while a return of 15 cents affords only 10 cents per yard in the other case. If this result be applied to the amortization of capital, it becomes possible to appraise the economic attractiveness of the two enterprises.

To those accustomed to other mining regions in which alluvial mining is predominant the richness of the gravels of the North is an insistent fact. The ground worked by drifting has averaged \$4 per yard of material excavated, the ground worked by open-cut methods has averaged \$2, the ground removed by the hydraulic elevators has yielded \$1.25 per yard, and the dredges have averaged nearly \$1 per yard; thus the gravel exploited in the North during the last ten years must have yielded \$3 per cubic yard. And not more than one-half of the gold was extracted. This is a large statement, but fully warranted. I could quote many cases of ground worked twice, even three times, that yielded as much at the second as it did when attacked in its virgin condition. The yield has been astonishing, but the methods have been crude and incomplete. There is going to be much profitable working of ground deemed valueless under the expensive and extravagant ways of the boom period. To engineers and operators possessing capital, in the form of experience and money, there is offered a splendid field for intelligent endeavor. The mining industry of Alaska and the Yukon is about to enter a new stage.

To deposit copper upon glass, one part of freshly distilled phenylhydrazine is heated in two parts of water until the solution is clear. A warm solution of cupric hydroxide in ammonia is added, followed by a hot 10% solution of caustic potash until a slight precipitate of cuprous hydroxide occurs. If the solution, in this condition, is brought in contact with a clean glass surface, a bright, perfectly reflecting deposit of copper forms upon it. The copper thus deposited is washed in an hour with water, then with alcohol, and finally with ether, in order to dry it without rupture. It is then coated with lacquer or varnish.

SMELTING CONDITIONS AT SALT LAKE.

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DE KALB.

Mutual distrust between the smelters and the ore-producers in the West has never been so great as at the present time. The miner has invariably accepted the smelter as a necessary enemy, instead of an ally. The basis for settlement between ore-shipper and smelter is unavoidably complex. In the application of sliding scales, penalties, bonuses, discounts, and direct charges, lie opportunities for over-reaching, which the shipper is prone to call by a harder name. Abuses have been common, but it is certain that they were far more frequent in the old days of cut-throat competition than they are under existing conditions when, speaking broadly, no open market exists. Strenuous efforts to obtain a wide patronage led to such cutting of rates that only by resort to sharp practice was it possible in many cases to win a profit. The miner is disposed to believe that the habit has been transmitted to the great corporations controlling the ore market today. On the other hand, the smelters are forced into greater caution in dealing with the public. They feel themselves under the ban, along with every other great combination of capital. They realize that they are regarded as legitimate prey by all who can benefit through harrassing them in the courts or by adverse legislation. On their side, they believe that the public has acquired the habit of persecution.

The day of the small smelting plant, however, may be said to have passed. With the increase in costs of labor and supplies, metals are necessarily produced on a lower margin of profit than formerly. Only by conducting operations on a vast scale can economies be introduced to meet the changing industrial situation. The spasmodic opening and closing of small plants reveals the practical impossibility of competition with the larger establishments; not only are costs relatively increased, but refining in a small way is economically impracticable. This applies with special force to copper. Before the metal is ready for market terms must be made with the giant corporations. It is a repetition of the ancient story of escaping Scylla to fall into Charybdis.

If the shipper distrusts the large operator, he distrusts the small one even more. He must secure a steady market for his ore in order to prepare for cheap mining; he hesitates to tie himself to an enterprise that may succumb at any moment, and leave him embarrassed for means to meet his obligations. The powerful company always exercises the greater attraction; though it may drive a harder bargain, it can be relied upon to fulfil its engagements. Great combinations of capital for smelting can be fought only with the weapon of combination among the mine operators, and such organizations have so far proved ineffective. They have lacked cohesion; perhaps they have lacked competent leadership; they certainly have never been inclusive of a formidable majority, partly because of wavering conviction among the mine-operators, and partly because the

large smelters from necessity have tied many producers by long-time contracts. Moreover, the smelter is a self-perpetuating enterprise, while the lives of mines are usually uncertain. The smelting situation is not unique; it is merely one phase of the industrial revolution taking place in every department of human activity throughout the civilized world.

Salt Lake City has become the most interesting smelting centre in America, and the battle wages there more hotly than elsewhere. It is centrally situated; it is at the cross-roads of commerce in the Middle West; it is surrounded by mineral districts of phenomenal reliability, yielding a great variety of ores, and offering opportunities for mining on a stupendous scale as well as for working profitably with modest capital. Both lead and copper are produced, the same districts containing mines of both metals. Basic ores predominate, and this extends the zone of attraction to Nevada, affording a market for the abundant silicious ores of that State. Large shipments are also made from Colorado to Salt Lake City, and from almost every mining camp in the Rocky Mountains. The conditions for economical smelting are ideal. In addition to the advantages already enumerated, enormous resources of coking coal exist only 125 miles away. Carbon county alone produces more than a million and a half tons of coal per annum, and the output for the State is approximately 2,000,000 tons. Run-of-mine coal laid down at Salt Lake City, Murray, Bingham Junction, and Garfield costs about \$3.25 per ton, and slack is available at \$2.75. As a result of these exceptional conditions smelting can be conducted at lower cost in the vicinity of Salt Lake City than at any other point in the Western States, and the smelting charges are actually lower than elsewhere. It has been asserted by representatives of both the American Smelting & Refining Co. and the United States Smelting, Refining & Mining Co., that the average net profit on the treatment of ores at their respective Utah plants does not exceed \$1 per ton. If this be true, it represents an inadequate return upon the capital invested. There has been active competition between these corporations, which has inured to the advantage of the miners. In spite of this rivalry, complaints are wide-spread, and a friendly understanding between these two companies is generally believed to exist. The circumstance that the United States company ships its silicious ores to the American Smelting & Refining Co.'s plant at Garfield is given as one evidence of such an understanding. At the beginning of the year 1908 great dissatisfaction prevailed throughout the State; it was freely asserted that a working alliance respecting smelter contracts had been arranged between the two dominant concerns. In the nature of things, operating as they were upon a narrow margin of profit, the terms offered on either side could not be materially different. Harrassed as they were by suits for damage from smelter fume, they declined uncontracted shipments, and this spread the discontent. Damage-claims from farmers against the United States company, now in court, exceed \$300,000, and similar claims against all the smelting companies in the

Salt Lake valley aggregate fully \$1,000,000. The American Smelting company distributed the sum of \$40,000 to the farmers as bonuses in consideration for the privilege of operating the lead plant at Murray. The United States company offered to distribute similarly the sum of \$90,000 for a like privilege at Bingham Junction; this was declined. A situation is thus revealed that calls for no comment or explanation. It was an important factor in deciding Judge John Marshall of the Federal Court to hand down a decree suspending the injunction against the Bingham Junction plant. He referred in his decision to this difference in the attitude of the farmers toward the two companies. He pointed out that the conditions in the voluntary agreement with the American company were less severe than those which the United States company offered to accept. The Court restricted the smelter to 0.75% sulphurous acid (SO_2) in the gases issuing from the stack, and required the complete removal from the fume of all arsenic, antimony, copper, lead, and sulphuric anhydride (SO_3). This decision was hailed with wild enthusiasm by the citizens of Bingham Junction. Whistles were blown, bells were rung, and the population turned out on parade headed by a brass band. The suspension of this injunction meant work for 750 idle hands, and a monthly distribution in wages of \$75,000.

Under these terms the Bingham Junction plant lighted the fires in its lead furnaces, but the copper plant, consisting of six blast-furnaces, five stands of converters, and a large reverberatory furnace, remains closed. The warfare against smelter fume hits the copper industry with particular severity. The Murray plant of the American company is also treating lead ores only, and the Highland Boy smelter of the Utah Consolidated company is abandoned. The building of the great plant of the American company at Garfield was the direct result of the agitation against the smoke nuisance.

Garfield lies 25 miles west of Salt Lake City, at the southern end of the Great Salt Lake. It is fairly remote from the older farming communities. The company purchased large areas in order to form a buffer zone against the agriculturists. The works are sheltered behind the northern spurs of the Oquirrh range of mountains, and the prevailing winds were expected to obviate difficulty with the farmers in the valley. But the "prevailing winds" proved unreliable, and difficulties have arisen. The company maintains a close watch upon the agricultural districts; a force of men detailed for this special duty is constantly observing the condition of vegetation, and taking samples of air for analysis. The region surrounding Garfield looks sufficiently barren to discourage agriculture, but no place seems desert enough to afford a safe asylum for a smelter. The farmer follows, attracted by the ready market, and, according to the smelters, by the hope of extra gains from 'smoke-money'.

The Utah Consolidated, driven out of the valley by the farmers, has sought a retreat on the western side of the Oquirrh range, in Tooele valley. A novel arrangement has been made to avert a clash with the

agriculturists. Instead of acquiring 'smoke-easements' on the surrounding lands, the company has bought 1200 acres in the immediate vicinity of the smelter site in Pine canyon, and in addition has secured options on large outlying areas, aggregating over 20,000 acres, which might be subject to damage. Ten per cent of the contract price is paid down, and the company may exercise its options and take title in future by paying the remaining 90%. If the options are not exercised the original payment is forfeit to the owners of the land. This enterprise has been heralded as a new competitor in the Utah field. It manifestly represents an invasion by the Amalgamated Copper Co., headed by John D. Ryan and Thomas F. Cole, and that, of course, means the Standard Oil Company. The construction of the works will be under the direction of E. P. Mathewson as consulting metallurgical engineer. It has been hinted that this is but one link in an extensive chain of contemplated operations throughout the West, including an agreement with Phelps, Dodge & Co., and that it is in opposition to the interests of the Guggenheims. Whatever of truth or falsehood may lie in this, the immediate purpose apparently involves little more than a relief for the Utah Consolidated. This company now transports its ore from the head of Carr fork, in Bingham canyon, by aerial tramway 12,000 ft., to a loading station on the Bingham branch of the Denver & Rio Grande railway. Thence it costs approximately 30c. per ton for freight to the Garfield smelter. The new works across the range will be only 15,000 ft. distant by aerial tramway, so that a large saving in transportation will be effected. In addition, it is claimed that the reduction in smelting costs will be 67c. per ton, yielding a total advantage of nearly \$1. The new smelter will be owned and operated by a corporation organized separately from the Utah Consolidated.

The entry of Standard Oil capital into Utah smelting, however, undoubtedly marks the beginning of energetic competition. Whether advantage to the mine operator will accrue, beyond the mere enlargement of his market, is doubtful. It is hard to see how the rates can be much further reduced. The inadequacy of plant sufficient to handle the ores offered is generally conceded, but the large producers are cared for under contract, and the small mines are not to be relied upon for a steady supply. At the beginning of the year a so-called "independent smelter movement" was started by F. Augustus Heinze. This was part of an elaborate scheme to extend the Mascotte adit to the Ohio copper mine, in Bingham canyon, which would then serve for drainage and transportation; to build a concentration works, and smelter; and to construct an electric railroad from Salt Lake City to Bingham, utilizing the Mascotte adit as part of the route. Funds were secured by a bond issue of the Bingham Central Railway Co., underwritten by the Metropolitan Trust Co. of New York. The issue was for \$3,000,000, in 40-year 6% bonds, redeemable in 1912, at the option of the company, at 105. The Mascotte adit has just tapped the workings of the Ohio mine, and the concentrating mill is being built, but Mr. Heinze has not become a factor

in the smelting situation. In January the Utah Mine Operators' Association, with John Dern as president, and Lafayette Hanchette, W. C. Alexander, George W. Ritter, and Ernest Bamberger, as the executive committee, passed resolutions favoring the independent movement, and as the Association represents 90% of the operating mines of Utah, Mr. Heinze apparently had a fair field. At the same time the Tintic Smelting Co. was busily engaged in the construction of a plant at Tintic, with a capacity of 400 tons of lead ore daily, and promises were made of a 48 by 108-in. copper furnace later. The plant was erected at a cost of \$250,000; was blown in during the first week of August; and after a brief campaign of two months was blown out, owing, it was claimed, to defects in construction. The Independent Smelting Co. also was organized, and rehabilitated the small Ogden

having available such avenues to market as lead out of the Salt Lake valley, is not easily touched by any metallurgical argument but the one of golden coin. He can raise alfalfa and make a good living, and he knows it. The shortage of smelting facilities in Utah today is due primarily to difficulties over smelter fume. The damage done has been grossly exaggerated; but the erection of smelting works in the centre of a rich agricultural region was certain to lead to trouble. The metallurgical industry of past years in the Salt Lake valley, however, was insignificant beside that which is growing up today. Bingham canyon has within the year taken its place in the ranks of the greatest persistent copper-producing districts in the world. Shipments of ore from that district now exceed 12,000 tons per diem. The vast areas of monzonite impregnated with chalcopyrite

Smelter of American Smelting & Refining Co., at Garfield, Utah.

smelter, which was blown in early in July. This is being operated as a custom plant. The Yampa smelter, in Bingham canyon, began the installation of a two-stand converter plant last summer. It is now treating about 700 tons of ore per diem, of which 200 tons represent silicious ores from Nevada. The Yampa Smelting Co. is a subsidiary corporation of the Tintic Mining & Development Co. The plant comprises two blast-furnaces, and three reverberatories, with converter equipment now in operation. The construction of the third reverberatory furnace, and of the converter plant, was undertaken in the face of an increasing number of damage suits by farmers. Complaints were filed affirming injury from fume 10 miles distant from the works.

The Utah rancher enjoys an independent position. He was there before the smelters; and while he appreciates in a measure the active demand for his products that increased local population causes, he could exist without the smelters. Any man in the arid West owning good land and water rights, and

and bornite, lying close to the surface, and available by steam-shovel excavation after stripping a small amount of overburden, have introduced entirely new conditions. The Utah Copper Co. alone is sending concentrate to the Garfield smelter yielding 4,000,000 lb. of copper monthly. The Boston Consolidated, with a mill little more than half completed, is turning out concentrate representing nearly 2,000,000 lb. of copper monthly. These merely mark the beginning of the new order. Under the aggressive and brilliant leadership of Samuel Newhouse, who has been the leading spirit in the Boston Consolidated, the Newhouse Mines & Smelters Co. is enlarging the copper industry of the State by developments of great magnitude in Beaver county, where a smelter will soon be erected.

The re-opening of the Ontario drainage adit, which was closed by caving in March, 1905, has given a new impetus to lead mining at Park City, which will become a more important producer than ever before. This adit, started in 1888, intersects the No. 2 shaft

of the Ontario mine at the 1500-ft. level, 15,494 ft. from the portal. It extends thence under the Daly West property, attaining a total length of 25,000 ft. The mines benefited by the adit are the Ontario, Daly, Daly West, Silver King, and American Flag. Developments in the neighboring Alta district indicate that it will soon yield an enormous tonnage of lead ore and concentrate.

In addition to normal growth in the Utah field, through increasing activity in the development locally of great mines, the restriction of operations at the Selby smelter on San Francisco Bay through injunctions obtained by the authorities of Benicia, and the abandonment of the plans for the construction of a great smelter at San Bruno, also on San Francisco Bay, have diverted business to Salt Lake. Opposition by the citizens of San Bruno to the erection of a smelter caused the American Smelting & Refining Co., after expending fully \$1,000,000, to remove the machinery and equipment that had been delivered on the ground, to the Garfield plant, where it is now in service. Thus have many circumstances contributed to augment the importance of the metallurgical industry in Utah. The year just past has been one of prosperity for the State, despite the financial stringency, and no other period in its history has been characterized by such activity in the erection of huge plants and in preparations for such enormous production as the year 1908. This is a tribute to the marvelous natural advantages in mineral resources and superior geographical position which this favored State enjoys. The work of the last two years has demonstrated possibilities that only those of keener vision had foreseen. It is now possible to look ahead far beyond the span of a generation. The opportunities for industrial achievement here seem endless. The attention of the leaders in American finance is being centred upon this field. It bids fair in its way to become for the West what Pittsburg is for the East. But a serious problem demands solution. The obstructive tactics that have embarrassed enterprise must cease. The future dominance of the Salt Lake valley as a smelting centre depends upon fostering conditions. If persecution continues, a limit will soon be set to the expansion of enterprise. Smelting cannot be conducted without the production of sulphurous gases, and the utilization of sulphuric acid in such quantity as to consume all that would result from complete condensation of the fume is impossible. Extraction of the sulphur by washing the gases would yield enormous amounts of acid liquors, for which an outlet would have to be provided. This might be done, and the State could afford to grant the free use of the Great Salt Lake as such a receptacle. It would seriously injure no one, unless it might be the manufacturers of salt, and to compensate them would be a smaller matter than for the State to lose the benefit of a normal development of its more magnificent opportunities. To a disinterested observer it appears that sympathetic co-operation is needed. If this spirit shall rule, nothing can prevent the Utah field from becoming the controlling influence in American smelting.

COLORADO IN 1908.

Written for the MINING AND SCIENTIFIC PRESS
By FORBES RICKARD.

While superlatives are not needed in recording the history of Colorado's mining and metallurgical achievements for the year 1908, this year witnesses a steady effort toward progress in the face of adverse conditions, such as low metal prices, lack of new discoveries, and a generally lower grade of ore production.

Statistics will show a decreased production in the last two years of from 30 to 35% in the tonnage of smelting ore handled from local points in the Colorado smelters; the figure is now 52,000 to 55,000 tons monthly, as compared with 80,000 tons smelter consumption in 1906. The Cripple Creek ore supply tends more and more to go to the mills, primarily on account of a lower tenor in gold; in part to better milling methods and the lower treatment charges brought about by the rate war that has been waging among the big mills for some time past.

The tonnage from Cripple Creek this year is probably the largest in the history of that district, though the increasing proportion of mill ore and consequently lower ton-value just about maintains the balance of production at \$12,000,000 to \$13,000,000 for the year.

Preliminary figures for Cripple Creek's output in 1908 are:

	Gold.	Silver.
United States Mint.....	\$10,071,867	\$14,843
A. S. & R. Co.	2,015,490	11,667
Totals	\$12,087,357	\$26,510

Sales of gold and silver bullion made through any other agencies will only fractionally increase this total.

The United States Zinc Co.'s spelter production for 1908 is 6,147,000 lb., at 4.58c., or \$281,532.

The diminishing output of silicious ores of a smelting grade from Cripple Creek accentuates an already serious shortage, which obliges the Colorado smelters to look to points outside of the State—notably Deadwood, in South Dakota, and Cobalt, in Ontario—for the silica required in the smelting mixture. Creede and Cripple Creek have been the mainstay for silicious ore since the production of the mines of this State began so largely to take the form of sulphide concentrates resulting from mill treatment. Mining of the silver ores of Creede is proceeding upon so narrow a margin of profit that a decline of two or three cents per ounce in the ruling price of silver might suffice to stop the operation of its principal mines.

The foregoing conditions, added to the fact that Utah and Mexico take care of their own ore production, are reflected in an unsatisfactory smelting situation in Colorado, a situation not attributable entirely to the evils of a monopoly that has grown out of the combination of the individual smelters into the so-called Trust. Some blatant Denver newspapers have attacked the American Smelting & Refining Co. and its methods, but this attack (semi-polit-

Aspen and West Aspen Mountain, Colorado.

Leadville, Colorado.

ical in its inception) has been made in such a way as to distort the facts, and it misrepresents the cause of the mine-owners and mine-operators of Colorado in their relations with the smelting interests.

A notable improvement that has grown out of the necessity for cheaper fuel comes through the erection of a modern and thoroughly up-to-date coal washing and coking plant by the American Smelting & Refining Co., at Cokedale, near Trinidad. With 278 ovens in use, the capacity of this plant ranges between 600 and 700 tons of coke daily. In point of construction this plant embodies several new features connected with the use of concrete.

Of the State as a whole it can be said that there is yet no indication of new districts coming into prominence, though that is always held as a hopeful possibility. While prospecting is being done all over Colorado, it seems that the old-time prospector is gradually disappearing, as the frontier moves north-west.

Concurrent with the exploitation of the mines in the well known districts of Colorado, there has unfortunately been practically no new prospect work going on. As a result the mineral resources of Colorado have been largely impaired; that is, as respects the better grade of mineral.

In the carrying out of the exploitation work of the mines which have been worked for the last thirty years, it has come to be almost a universal practice when the mines fail to pay under the operation of the mining companies themselves that the ground has been sub-leased, and it has been due to the energetic work of such lessees and their willingness to take large chances that new orebodies have been brought to light which, however, as a rule have been of markedly lower grade than were those which were produced under company management. In order that these lower grades might find a market, and driven by dire necessity to make use of every mineral resource which the State might furnish, the American Smelting & Refining Co. has consistently worked to the end of bettering its plants so that it might handle the lower-grade ores and still leave a profit for the producer. The history of smelting charges for the last ten years in Colorado will consequently point to an unwavering and continuous reduction in treatment charges which has enabled the production of low-grade material which under other conditions could not have been marketed, especially in view of the concurrent lowering of metal quotations.

Railroad extensions that are active in connection with the Denver, Northwestern & Pacific Railroad, popularly known as the Moffat road, and the Denver, Laramie & Northwestern, are greatly benefiting coal and land interests throughout the country tributary to them. The Yampa coalfields particularly welcome the advent of the Moffat road, which affords them an outlet to the market, for which they have for years been waiting.

Considering the mining districts separately, the one new development of importance is that of the Frank Hough Mining Co.'s mine, on Engineer mountain, in Hinsdale county, where an old mine producing in the years from 1877 to 1885 is being re-

opened with successful results after long abandonment. The ore shipments carry the extraordinarily high average of 25 to 35% copper, with substantial silver assays, besides gold and lead contents. At Leadville the Ibex company, through lessees, is maintaining the production of last year. The district generally is waiting on the Yak Tunnel extensions under Breece hill. In the San Juan region the Telluride mines are doing well; while from Silverton comes a steady yield of gold and concentrates evincing the usual activity of this district. The Aspen output has been fluctuating widely with the variation in the Smuggler production, which the low silver quotation is holding in check.

The following gives the metal production of the Colorado plants of the American Smelting & Refining Co. for the last three years:

		1906.	1907.	1908.
	Tons smelted,	829,426	795,849	555,313

Copper, cents per pound	20	13

The rare-mineral resources of this State have for several months been attracting much attention, less to tungsten than to vanadium. From the fact that the Boulder county tungsten production has in recent years taken so prominent a place as to account for nearly 80% of the production of the United States, and approximately 30% of the world's tungsten product, this mineral resource has been well advertised; the vanadium mineral resources are comparatively undeveloped and but little known. The extended use of vanadium in high-grade steels is prompting the development and suggesting the utilization of certain deposits of vanadiferous sandstone in the southern part of the State, which, once that the commercial question is successfully solved, represents an ore supply of no small proportions.

This State's resources in the production of rare metals, in tungsten, vanadium, and uranium, is an asset that is destined to figure more prominently in the future than it has in the past.

The stone industry, particularly in the past year, has been making great strides; in the Yule and the Turkey Creek quarries, respectively, there is being mined marble and sandstone that is fast supplanting importations of building stone from parts foreign to Colorado.

Cost of diamond-drilling in the mines of the British Columbia Copper Co., in the Boundary district of British Columbia, during 1906 and 1907 was \$1.705 per foot. The average depth of holes was 81.3 ft., and the diameter of the cores was 7/8 in. One carat of diamonds, the average cost of which was \$66.46, drilled 111.9 feet.

THE REAL EL Dorado.

Written for the MINING AND SCIENTIFIC PRESS
By F. LYNWOOD GARRISON.

The word 'Eldorado' has become part of our English vocabulary and is defined by the Century dictionary as "a country rich beyond all precedent in gold and jewels, which the early Spanish explorers believed to exist somewhere in the New World and which Orellana averred that he had found in his voyage down the Amazon in 1540-41. This was soon disproved, but the search was continued down to the eighteenth century, and the name has become a synonym for any region said to abound in the means of easily acquired wealth." Probably few persons are aware of the origin of the word, and that it is derived from substantial fact; that it is not a mere myth connected with the early history of South America. The following narrative, sketching the history of the Eldorado, will serve as a prelude to a description of the alluvial gold deposits of the Cauca valley in the State of Antioquia, Colombia; these deposits constitute a part if not the heart of the district that furnished the gold which enabled the Indians of the Bogotá plateau to carry out certain curious ceremonies that originated the name 'Eldorado.' For the facts of this fascinating story I am indebted to A. F. Bandelier, whose little book, 'The Gilded Man' (Appleton & Co., New York, 1893), contains some of the most interesting data connected with the first Spanish settlements in America. Fact and fable are so often inextricably confused in the history of the Spanish conquest of South America that it is at times difficult to know what to accept as correct. The story of the Eldorado as related by Bandelier has evidences of truth, hence I venture to re-tell it for the purpose of introducing my own story. It must be explained in this connection, that the old Spanish name for the large country now known as Colombia was New Granada, consequently all the old writers refer to the country by this name.

During the years 1525 to 1530 a story was current among the Spanish settlements along the Caribbean coast of New Granada and Venezuela that a certain tribe of Indians living in the interior had such an abundance of gold that with it they powdered afresh each day the body of their chief. This legend of *el hombre dorado*, or the gilded man, embellished in the telling, became a kind of wayside yarn, a tavern story never too fantastic to find a host of believers in that age of superstition and ignorance. The word *hombre* was dropped in the course of time, and the term Eldorado as we know it was evolved. The legend was based on fact, but the word Eldorado has to this day been a gilded will-o'-the-wisp to lure the farmer from his plough, the mechanic from his bench, often to misery and destitution, and seldom to fortune. The very word 'gold,' the sight and feel of the precious yellow metal, has for ages affected the mind of man like a potent spell, especially the improvident and shiftless, ever on the alert for riches easily and quickly acquired.

The various efforts of the Spanish to plant colonies

on the Isthmus and in western New Granada had but insignificant results until Balboa in 1511 assumed direction of the Colony at Darien. Balboa seems to have heard in some way of a wealthy Indian tribe that lived on the sea-coast to the south and used large 'sheep' as beasts of burden. Prescott assumes that Balboa learned in this way of the riches of Peru, but Bandelier thinks it more probable that this notice refers to the semi-civilized tribes of central New Granada, that carried their salt over beaten mountain paths to the cannibal tribes of the Cauca valley, receiving gold in exchange. The centres of primitive trade were naturally among the more civilized tribes, for they had the greatest number of wants; they were agricultural, and consequently possessed fixed abodes, or villages; in New Granada such centres appear never to have been in a gold-producing district; the more civilized tribes accumulated, by both trade and war, the metallic treasures of the wilder regions about them. The locality where this rich tribe of Indians lived was eventually determined to be on the tableland of Bogotá, in the Province (now State) of Cundinamarca, in the heart of New Granada. These people were known as the Muysca (Chibchas), who lived on the high temperate plateau of Bogotá. As this upland plain could only be reached through narrow ravines, these people were more or less isolated from the surrounding savage cannibal tribes, with whom they appear to have been in frequent conflict. Yet these hostilities did not prevent an active reciprocal trade, and as a consequence gold was accumulated to superfluity by the comparatively civilized Muysca. These people appear to have understood the art of hammering gold and casting it into tasteful shapes, for they adorned with it not only their weapons and clothes, but the interior and exterior of their temples and dwellings as well. The numerous lakes of the plateau were regarded by the Indians as holy places, each one being considered the seat of some special divinity to be propitiated by throwing gold and emeralds into the water. One of these lakes, known as Guatavita, became thus famous as the spot where originated *el hombre dorado*, or the gilded man. This lake is north of Bogotá, on the apex of a conical hill, probably the crater of a small volcano; it is some 8 or 10 miles in circumference, and has a depth of 40 to 50 ft. The Indians living in the immediate neighborhood of this place at one time constituted an independent tribe, which upon the occasion of choosing a new chief observed an imposing ceremony: the new chief being carried upon a chain hung with discs of gold, his naked body having been annointed with a resinous gum and sprinkled all over with gold dust. It does not appear from the narrative that the chief was dusted in this manner each day, or that he habitually wore such adornment. When the chief and his attendants reached the shore of the lake, they stepped upon a raft (*balsa*), and proceeded on it to the middle of the lake. There the chief plunged into the water and washed off his metallic covering, while the assembled company with shouts and the sound of instruments threw into the lake the gold and jewels they had brought with them.

The sacrifice completed, the chief returned to the shore and to the village, where the festival closed with dancing and feasting. This ceremony appears to have died out about the year 1740, when this tribe of Guatavita Indians was overcome and became tributary to the Muysca of Bogotá.

The search for the Eldorado in South America in the early Spanish days was energetic, and eventually led to the settlement of the Bogotá plateau, which is now the capital and centre of civilization of the Republic of Colombia. It is a singular historical fact that the first man seriously to undertake this wild adventure was the new German governor of Venezuela, Ambrosius Dalfinger, of Ulm in Swabia. It may not be generally known that the Emperor Charles V in 1529 leased the Province of Venezuela to the German house of Bartholomeus Welser & Co., of Augsburg, and that many Germans were among the earliest pioneers in South America. They were not then, as today, mere traders, risking little or nothing in the development of the country, but had among their numbers men of enterprise and courage, ready to embark upon expeditions promising adventure and booty. Dalfinger's hunt failed of its quest, although he reached the edge of the plateau of Bogotá. A number of subsequent Spanish and German expeditions were also disastrous. On the same search in 1536, the Spaniard Quesada started from Santa Marta on the Caribbean coast, and after enduring incredible hardships, and overcoming tremendous obstacles, succeeded in reaching the Bogotá plateau in the early part of 1537. Quesada found the Indians here possessed of an enormous quantity of gold, which of course soon passed into Spanish hands. In August, 1538, he founded the present city of Santa Fé de Bogotá, which consequently owes its origin to man's quest for gold, although it is far distant from any gold-producing district that could have been worked by the primitive inhabitants. With the conquest of the tribes occupying this plateau, was secured the last great treasure of gold that awaited the Spaniards in the New World. Their greed, however, was not satiated by this success, they thirsted for more; then again, year after year, arose like an avenging spirit the legend of the Eldorado, leading other and less fortunate men to a bootless quest into the unknown regions of the interior. In 1534 Heredia started southward into the regions of San Jorge and Sinú, and in 1535 he reached the Cauca river. In this direction went also the expeditions of Cesar, Vadillo, and Robledo, conquering a great part of Antioquia and the upper Cauca valley. Heredia's expedition is said to have yielded to each of his soldiers spoil equivalent to \$70,000.

Anyone who has had personal experience in the wilds of South America cannot fail to be impressed by the hardihood, courage, and perseverance of these old Spanish and German adventurers; nothing daunted them; they had no quinine to check the awful fevers in jungle and swamp; no netting protected their bodies from the nerve-racking mosquito; medicine and surgery were alike crude and

rude in that early day; instruments of precision, preserved foods, and all the paraphernalia which we now think indispensable for expeditions of this kind were unknown to them; they suffered, usually failed, often died of hardship; some expeditions returned with less than half of their original numbers. These men of iron were brutal and avaricious toward the natives, killing and robbing them without stint; their sins we hear much about, but it is impossible for any fair-minded man to withhold from them admiration for a bravery and steadfastness unsurpassed in the annals of gold-seeking. Success meant for them castles in Spain, but to few were such vouchsafed. After the accumulated stores of gold were taken from the Indians, the Spaniards naturally sought to find the source of these rich treasures; this was soon determined to have been chiefly the alluvial deposits in the valleys of the Cauca river and its tributaries. To wash this gold required hard work, which the Spaniards themselves would not or could not do, hence arose a gradual enslavement of the Indians for this purpose. An overmastering desire to get rich quickly and leave the country was not compatible with kind and humane treatment of the natives, hence they were literally driven to death by their masters. It is stated on good authority that so great was the mortality among the Indians that whole districts were depopulated, causing an abandonment of the mines in many places and a rapid decrease in the production of gold. For two centuries the Indian tribes were compelled to give one-seventh of all their able-bodied men to work in the Spanish mines in slave-gangs. Efforts were made to replace these Indians with negro slaves from Africa, but the experiment does not appear to have been successful, although unquestionably there was a large influx of negroes, as evinced by the present predominant type of inhabitants to be found in the lowlands of Colombia.

The Copper Queen Co. is probably the lowest-cost copper producer in the United States today, which would indicate that its copper costs are not above 7c. per pound. Its smelter is now producing at a rate of better than 8,000,000 lb. of copper per month, or 96,000,000 lb. per annum, though a portion of this production represents copper from its Mexican properties. It has been the policy for some time to pay an annual dividend of \$17 per share, which calls for the distribution, as profits, of \$3,400,000 per annum. There are 200,000 shares in this company, par value \$10, and there are but 14 stockholders, all connected with the Phelps-Dodge firm. The following is a complete list of the Phelps-Dodge companies: Copper Queen Mining Co. of Bisbee, Old Dominion Copper Mining & Smelting Co. of Globe, Detroit Copper Mining Co. of Morenci, Moctezuma Copper Co. of Nacozari, Mexico, Indiana Sonora Copper Mining Co., of Cananea, Mexico, Almagre Copper Mining Co., United Globe Mines of Globe, Arizona, Commercial Mining Co., Dawson Fuel Co., Dawson Railway Coal Co., Stag Canyon Fuel Co., New Mexico Fuel Co., El Paso & Northeastern R. R., Alamogordo Lumber Co., and Southwestern Mercantile Company.

MINING IN THE MALAY STATES.

Written for the MINING AND SCIENTIFIC PRESS
By E. SEABORN MARKS.

The Federated Malay States are situated in the southern part of the Malay Peninsula, which extends from Lower Burma to Singapore. The country is little known to the world at large; nevertheless, it produces over 60% of the world's output of tin, besides exporting rubber, coffee, copra, and other tropical produce. Mining has been the staple industry for hundreds of years, and up to recent times has been mainly in the hands of the Chinese pioneers. It is to this race that the prosperity of the Peninsula is due, while even at the present time it is estimated that fully 85% of the yearly production (amounting in round figures to \$39,000,000) is contributed by Chinese enterprise and labor.

The Federated States of Perak, Selangor, Negri, Sembalan, Kelantan, and Pahang are ruled by the rajahs of the original people, the Malays. The country is under British protection, the general policy being directed by the British Colonial Office, represented locally by a Resident-General, residing at the capital, Kuala Lumpur, and under him there is a British-resident for each State. There is a Mines Department under the direction of F. J. B. Dykes and an efficient staff of engineers. This is a Federal institution; it controls the industry, safeguards individual rights, and is the most important government office in the country. A rental of 56c. per acre is charged for mining land, for leases that are issued for a period of 21 years, but renewable in perpetuity. A tax of 10% is levied on the gross value of the tin produced; this also varies slightly with the market price of the metal.

The funds obtained from this and other sources are spent entirely in developing the country by aid of roads and railways, besides generally advancing the interests of the community at large; the surplus stands to the country's credit and at the present time amounts to about \$50,000,000. There is a line of railway running from the northern end of the States to Singapore, the most southerly portion of the line through the State of Johore being under construction and nearly completed. The wagon-roads are well built and maintained; this makes it possible to travel pleasantly by automobile.

The climate is tropical, the temperature varying but little during the year, day or night, and the air is heavily laden with moisture. The thermometer stands as a rule between 80 and 90° F. in the shade. Rainfall is heavy, averaging 100 in. per year; in consequence, the country is covered with a thick, impenetrable jungle, making it impossible to leave the roads or paths without cutting the underbrush. Under these circumstances, prospecting is both arduous and difficult; nevertheless, new mineral deposits are continually being discovered.

The native of the country is the Malay, formerly known as a pirate. Under British rule the natives now lead a quiet and peaceful life, in their *kampongs* or villages; they never work unless it is to cultivate

rice and grow a little fruit, besides fishing for their immediate wants. The Malay language is spoken universally by everyone and is the business language of the country. The Chinese, speaking different dialects, use it among themselves, and the European uses the language with either Malay or Chinaman. It is absolutely necessary, therefore, for anyone wishing to do business in this country to learn Malay; but this is easy.

The Chinese now outnumber the Malays. The white population is small but slightly on the increase, with the introduction of more scientific methods in the general industries of the country. This is not, however, a white man's country, as fever and other tropical ailments are prevalent, but with a periodical change to more temperate zones the European can retain fairly good health.

As has been previously stated, tin mining is the staple industry. The methods generally adopted by the Chinese are primitive, of course. Improvement is, however, evident. Today a mine worked on or-

Federated Malay States.

thodox Chinese lines may be seen side by side with the latest Australian mining practice.

A little gold is found in Pahang and Kelantan, but it does not amount to much; tin is practically the only mineral produced. It occurs in the form of cassiterite or tin oxide, which is found for the most part in alluvial deposits. Although placer mining predominates in the State of Pahang, the Pahang Consolidated operates what is probably the largest and richest tin lode in the world, the mine being equipped with an up-to-date stamp-mill and concentrating plant; electrical power for all purposes is generated by water. One or two small lode mines also exist in this State; in fact, the whole of the eastern side of the peninsula divided by a ridge of mountains is reputed to contain deposits of tin-bearing rocks, which in the future will doubtless be prospected and worked. Reference is directed to the tin lode deposits in Sidney Fawns' book, 'Tin Deposits of the World.'*

The main scene of activity is in the western States

*Published by the Mining Journal, London, 1907.

of Perak and Salangor, where the mining is confined to placers. From time to time gash-veins have been opened up with a great flourish of trumpets, but no lode of persistent value has been discovered. Nor are the alluvial deposits uniform in character. Tin has been accumulated in the ordinary way in the river-beds. Lacustrine deposits also exist showing water-worn wash, and accumulations of angular to sub-angular detritus, besides alluvial clay that carries tin in places.

Fawns, in his classification of the deposits, refers to alluvial 'deep leads.' In the true sense of the term, none of these has been found, there being no regular leads or runs of tin gravel. The nearest approach to a lead might be seen in the property of the Tronoh Mines, but this is probably a depression in the limestone about 150 ft. wide and 2000 ft. long, and from the shape alone this might be taken for an alluvial lead.

Unfortunately no detailed geological survey of the country has been made, nor does there appear to be any definite theory as to the origin of the tin accumulated in the alluvial deposits. The predominating rocks are granite, schist, and limestone. The granite is locally reputed to have been the matrix, but there is no direct evidence of this, and it would appear as likely that the schist had furnished a considerable portion of the tin.

The tin-bearing area of the two largest and most important districts, Kuala Lumpur and Kinta, have a bedrock of limestone exclusively. The huge holes and pockets, often 200 ft. deep, and the surface generally of this limestone has been entirely covered with tin-bearing debris. The Kinta field, the larger and most important, is fully 12 miles wide and about double as long. Near the town of Ipoh small pipes of tin ore occur in the solid limestone itself. This is a rare occurrence. An article appearing in the *Journal of Geology* entitled 'The Tin Deposits of the Malay Peninsula, with Special Reference to Those of Kinta,' by R. A. F. Penrose, is worthy of reference.† A few English companies within recent times have started operations, but it is only within the last few years that men of experience and talent have directed the work; it has not been unusual to find a white man working with the same methods as the Chinaman.

In the lowest rung in the scale of evolution of Malay mining, we have the interesting Chinese *lom-bong* or open-cut, illustrated in Fig. 1. Everything is done by hand labor with the exception of pumping the water from the ground. In all cases steam-power or gas-producer plants are used for pumping. The method of mining the ground is as follows: An excavation is made and light bamboo trestle stagings are built at different heights and angles to the face of the ground in the direction in which it is to be worked; the coolies travel backward and forward across these trestles, dumping the overburden on the ground already worked and carrying the *karang* or pay-dirt to the concentrators. The mode of car-

rying the material is that usual to the Chinese: A pole borne on the shoulders, with a basket hanging at each end, enables the coolie to carry 30 to 40 lb. on each trip, the distance being about 150 ft. A mine worked in this manner resembles an ant-heap. The biggest mine thus operated carries a face 2400 ft. long and 4000 coolies are engaged. Out of every hundred coolies employed, 60% carry, and 40% break the ground and load the baskets; one tool only is used, called a *chonkal*. It resembles a hoe and does the work of a pick and shovel.

The method of concentrating is equally primitive, but more effective. The pay-dirt is dumped into a washing-box to which it is fed with a rake; this box is called a *land-chute*, and is illustrated in Fig. 2. The box when empty resembles a coffin in shape. It is from 10 to 14 ft. long and at the head would be about 2 ft., widening to 3 ft. 6 in. or even 4 ft. in the first 5 ft. of its length, and drawn in at the bottom to about 1 ft. 6 in. A riffle is placed every three or four feet, there being not more than three riffles to a box. A water supply is provided in quantities as required, and the grade is usually about 1 in 20. To concentrate in this box as the material is raked in, a coolie keeps dragging the gravel against the current with a *chonkal*, and as the concentrate is collected in the riffles, it is dug out and re-treated in a similar box, but without any riffles. From 300 to 500 lb. of the rough concentrate is cleaned at a time. The operation when completed results in an ore assaying from 65 to 72%; this is bagged ready for market.

The Chinese are exceedingly clever in the manipulation of these boxes and the loss of tin is small. The tailing from the re-dressing was mostly black sand and was found on assay, from different mines, to yield from 1 to 5% tin. When the quantity of black sand remaining is taken into consideration, the loss in the operation is small. The mine and concentrating works are under one manager, who sits most of the day in his office. He deposes his work to *kapalas* or foremen, each of whom has charge of an insignificant number of coolies. The mines are worked by Chinese companies or individuals, but principally by the individual, who is generally a rich and influential man. He is called a *towkay*.

The method of working is simple and primitive, but when it comes to paying for the work, the arrangements are intricate. The mines are worked on the 'truck' system, under which laborer and miners were sweated, in the first part of the nineteenth century and before, in England. It is a point which is being contested at the moment among the Malay States Government officials, as to whether Chinese mining would be equally prosperous and the coolies better off if this system were abolished by law.

The Chinese employer settles with his coolies every Chinese New Year and again in six months, there being therefore two pay-days per annum. All the coolies are housed on the mines in sheds suited to the climate and fairly clean. Each clan, or Chinese speaking a different dialect, is kept apart in what

†Abstracted by the author in *The Engineering and Mining Journal*, June 20, 1903.

are called *kongsis* or companies. This is to prevent, as far as possible, any conflicts. Feuds generally exist, but rioting is not frequent, although the coolie has a lot of time on his hands, only working six hours per day. Food is supplied in the shape of rice, and every six weeks there is a feast-day, when extra rations of pork and vegetables and perhaps some cakes are supplied. Pork is generally eaten at one

become *towkays*. It is a rare occurrence that a principal fails to meet his obligations; when this has been known, the non-payment of wages creates little fuss or bother; the coolie stoically takes the position as he finds it, says it is fate, in all probability burns a joss-stick or two to propitiate the evil spirits occasioning the bad luck and moves on to find work elsewhere.

Should the *towkay* not wish to feed his coolies, this is done by the contractor, who, while working with the party, takes a small percentage of the money earned besides the share coming to him for his labor, and in turn looks after the catering. On the termination of the contract, an account of the cost of living is prepared and the balance is divided among the workers. Should this plan be adopted, the contractor, on taking his contract, receives the sum of \$3 per coolie he is to employ. He has, however, to give a guarantee for this advance, and is charged no interest, the amount being taken into account as against the contract. The cost of mining under the foregoing conditions varies: a contract is let at a price per *chang* equal to 30 by 30 by 1½ ft., or 50 cu. yd., an average price being \$4.17 per *chang* for stripping and dumping 150 ft. back from

the working face, or 8c. per cubic yard. The pay-wash is contracted at \$5.25 per *chang* delivered at the land-chutes. The cost of washing, etc., varies greatly, ranging from 10 to 20c. per yard. The expert coolie on the land-chute gets 50c. per day

Fig. 1. A Chinese Open-Cast Mine.

meal each day, the coolie supplying the meat himself.

There are few day laborers, the work being performed mainly on contract. On some mines indentured laborers are employed. Charles M. Rolker has published details of contracts.† A man takes a contract and has a party of coolies to work with him. The mine-owner deals with the one man only. Any coolie can draw an advance on account of his wages, which are due at the end of six months, but should he make a draw he has to pay interest. At the end of the first month he pays only 30% in other words, he receives 70 cents and is charged with one dollar. In the fifth month the interest is reduced 5%; thenceforth there is a reduction of 5% each month. In the sixth month the *towkay* magnanimously pays him his money with no interest charged. Attached to all the mines there is a store (where all the coolies have to deal), opium dens, theatres, and houses of pleasure are all provided by the genial boss; in these places the coolie is further bled of his earnings. This sounds terrible to anyone who has not lived in the country. It is, however, surprising to find how happy and contented the coolies are; their average earnings are about 25 cents per day, out of which some of them provide themselves with all sorts of luxuries, and save money as well, and in their turn

Fig. 2. Chinese Sluice-box in Operation.

and the ordinary laborer 25c. and rice. The value of the ground being worked in the big mine previously referred to, is 4 lb. black tin per cubic yard. This mine has produced in the last three years 41,000 piculs of 70% ore (16.8 piculs equal to one long ton) of a gross value of \$895,000, the net profit being \$366,000. The working cost, in this case, therefore, represents 60% of the gross value.

†Trans. A. I. M. E., Vol. XX. 'Alluvial Tin Deposits of Siak, Sumatra.'

A Chinaman estimates that with his methods of working he can treat ground 40 ft. deep from top to bottom, including 10 ft. of pay-dirt on the bottom, the 'pay' being worth 10 *piculs* per *chang*, equal to 6.66 lb. per cubic yard, or an average from top to bottom of 1.66 lb. black tin per cubic yard.

The foregoing describes a mine working with a free wash; when there is 'puggy' wash or clay, the primitive method of treatment is as follows: the overburden is carried and dumped as before; the pay-dirt is puddled by hand on the bottom of the mine by coolies; sufficient water is added from time to time to form a liquid paste, which is ladled up the face of the claim into troughs placed from four to six feet, one above the other, until it passes into the land-chute, where the contents are extracted in the ordinary way. A mine working on this principle is shown in Fig. 3. This mine produces about 200 *piculs* of concentrate per month and the working costs are about 25c. per yard.

The method adopted to ground-slauce a bank 15 to 20 ft. high is amusing. Fig. 4 illustrated this method, known as a *lampan*. From the photograph it will be noted that the face of the tin-bearing ground is cut in steps or else has an incline of about 70°. A row of coolies starts at the top of the incline and with a long broad-headed spear cuts steps about a foot deep to the bottom. The material broken in this operation falls to a tail-race below, is sluiced away, and the tin collected. On the return journey up the face the coolies destroy the steps they cut in descending; on arrival at the top, the incline is again ready for a further series of steps to be cut, to be destroyed again, and so on, the process being continued. The work is supervised by an overseer, who sits under an umbrella and smokes a water-pipe.

Where a small head of water is obtainable, there a bamboo pipe-line, a canvas hose, and a brass nozzle will represent Chinese hydraulic mining.

But there are also large hydraulicking plants, washing away the sides of the hills; these have pipe-lines from four to ten miles in length, notably at Gopeng and Bruseh, which are English-owned mines. The latter is of interest; it is under the supervision of a Californian engineer and is the biggest hydraulicking mine in the Peninsula, and, when the conditions of working are taken into account, it ranks as a cheaply worked mine. A pipe-line seven miles long supplies water under a head of 350 ft. to three monitors using 3-in. nozzles. The hydraulicking ground is 300 ft. wide and 150 ft. deep. The formation is a tough and fine-grained sandstone, resembling a schist, in the bedding of which are segregations of quartz carrying tin ore. The formation looks like a lode. The face is T-drifted and three or four cases of dynamite exploded at the ends; after each explosion the monitors get to work washing away the débris, while battering and breaking the lumps of rock against the face. A ground-slauce leads to a sluice-box fitted with angle-iron riffles 350 ft. long, 4 ft. wide, with a grade of 1 in 24. As may be imagined, much time is taken in cutting up the bottom; the mine, however, produces 600 *piculs* of

concentrate per month. The boxes are cleaned up every three or four days; this takes three hours. The greater portion of the tin is collected in the first 40 ft. of the box, water being supplied at the rate of 750 cubic feet per minute. The ground carries one-third of a pound of black tin per cubic yard; this is equivalent to 11c. The total working cost is 6c. per cubic yard. Added to the difficulty experienced in the hardness of the ground, there is not a good get-away for the tailing, which is raised by a hydraulic elevator and carried farther down the valley, when the accumulation at the end of the boxes has become excessive.

The first improvement in open-cut mining was introduced only within the last few years; I refer to mechanical haulage. An inclined tramway operated by a steam-winch is run from the dressing-floors to the bottom of the mine. At the bottom of the mine tracks run to different parts of the face, where the trucks are filled by hand and pushed by the coolies to the station to be drawn to the surface. This naturally reduces the labor. With the improvement in the method of hauling we find a corresponding betterment in the dressing-plant. In free ground the wash is tipped into a hopper, and then passes to a long sluice-run fitted with riffles. Should the wash contain clay it is dumped into steam-driven puddlers with bottom-discharge overflowing into a sluice-run. To expedite puddling with very stiff clay, a rotary machine treats the material before it passes into circular puddlers. The concentrate in either case is cleaned in a land-chute, and it is doubtful if this latter method could be improved upon locally. Working under these conditions, the costs vary from 15 to 20c. per cubic yard.

In some of the rich placer deposits the Chinese have resorted to mining by shaft-sinking, but this method is not much in vogue, being slow and expensive. The plan is to sink innumerable shafts side by side; the Chinaman will not work away from his shaft, in drifts. The method is also wasteful, a considerable portion of the ground remaining standing between the shafts. In the early days of mining the Chinese for the most part only worked with shafts, and localities formerly riddled with shafts are now being re-worked at a profit. More advanced methods are now adopted in the Malay States, and each year sees some slight improvement, it being recognized that the exhaustion of the richer deposits necessitates increased economy.

In Kelatan there is a fleet of dredges, with buckets of 4½ cu. ft. capacity, of the New Zealand type, digging for gold. These machines are poorly designed and badly operated, according to all accounts, and the industry does not amount to anything. An 8-ft. bucket-dredge with a hull on the lines of an ocean-dredge is working the sea-bottom of the harbor at Tonkah; this plant is said to be doing good work, sea-water being used in the concentrating. It is a private enterprise and no details are forthcoming as to the results achieved.

The most recent innovation has been the advent of a pump-dredge from Australia. The pump-dredge,

that is, hydraulic elevating and sluicing with centrifugal pumps, was started some 15 years ago in Victoria, Australia, working for the most part such ground as could not be treated with a bucket-dredge. This has become an important industry in Australia on the old gold and tin placers. The device may be described as follows: There is a square-built pontoon or barge of dimensions to suit the plant it has to carry. The structure requires to be strong and stiff enough to bear the machinery, and is braced accordingly. In this it varies from the bucket-dredge pontoon. On the barge at each forward corner are placed pumps, to raise water and gravel, respectively; each pump is driven by a separate engine of sufficient power to do the work required. Besides the engines and pumps there are the necessary boilers and accessories and a small electric-lighting installation. This is all the machinery required on a steam-driven pump-dredge. The plant when at work always rests on the bottom or bedrock, and

pump, the barge is floated up to them by flooding the pit; when a desired position is reached the water is pumped out and the dredge rests on a bed prepared for it. Work is then re-started and the ground previously excavated is filled in with tailing. Ground when worked in this manner is left much in the same condition as it was before it was touched, and is not destroyed like that turned over by a bucket-dredge, for the reason that most of the fine and light sand remains on the surface; therefore, under this system there is no destruction of land, watercourses, or river-channels, as may be the case in other classes of hydraulic mining. The water can be filtered should it be desirable to run it away clear, or else, as is at times practised, is used over and over again. The cost of mining varies with local conditions, from 6 to 14c. per cubic yard, the chief item being the power required to raise the gravel. The wearing parts are in the gravel-pump liners. These are made of manganese steel and have to be renewed from time

Fig. 3. Working a Deposit of Clay-Wash.

Fig. 4. Chinese Ground-Sluicing.

is floated only when the position has to be changed. The intake of the gravel-pump leads to a sump in the bedrock, and the outlet or discharge is through a pipe to a series of sluice-boxes placed above the barge at such a height as may be required according to the depth of ground worked. The sluice-box is from 100 to 150 ft. long and has a fall of about 1 in 20. Water from a ditch on the bank is conveyed to the monitor-pump and is forced through a pipe-line to monitors, which break down the ground, the water sweeping the materials along a flume to the gravel-pump, which elevates the gravel to the boxes, for washing; the tin is extracted and the tailing stacked behind the plant. Rough bouldery ground, with hard rock-bottom that a bucket-dredge could not touch, is successfully worked by this plant.

While in operation, the plant rests on the bottom; this helps when cleaning the crevices and scraping the bedrock. Big boulders are not handled, but may be turned over, so as to get at the surface underneath. A dredge of this kind will work for six months at a time and continue in operation without being moved, stripping several acres. When the working-faces become too distant from the gravel-

to time. In places, in very deep ground, pumps are worked in stages, one above the other, the lower pump lifting the gravel to another, which raises the gravel to the sluice-boxes.

One of the largest plants in the States is at Tan-jong-Rambutan. This has a 15-in. centrifugal gravel-pump, taking boulders of 15 in. diam. It weighs 18 tons and is capable of lifting 2000 yd. of gravel, plus the necessary water for washing, per day. The lift is 50 ft. A 12-in. monitor-pump is used and the compound-condensing engines develop 500 hp. The sluice-boxes are 120 ft. long, 9 ft. 6 in. wide, and 18 in. deep, fitted with a riffle or block 6 in. high and 1½ in. wide every 20 ft. This box has been found by experience in Australia to be more efficient than one fitted with riffles for its whole length. Coolies are kept in the box raking up the stuff all the time. The rough concentrate is cleaned in a land-chute; in Australia, this is jigged. This ground is unsuited to bucket-dredging. The working cost, including all charges, is 8c. per cubic yard.

The Teka plant has two 15-in. gravel-pumps and no monitor-pump. This plant was started recently and the working costs are claimed at 6c. per cubic

yard. The pumps treat 4000 yd. of gravel per day.

At Lahat there are three 15-in. pumps driven by electricity generated at a central station on the mine. The ground is 120 ft. deep and two lifts are used for elevating the gravel to the boxes. These plants have only started work within the last four months.

The details herein given are offered as a description of the various methods of mining in vogue in the Federated Malay States. There is little to be learned from the Chinese, unless it be perseverance and energy. English capital is being invested in the country and with it are coming more advanced ideas. The dark ages of Malay mining are past. The future prosperity of the country will depend upon the exploitation of the low-grade deposits on a large scale by mechanical methods.

PROGRESS IN BRITISH COLUMBIA.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE A. OHREN.

Looking back over the twelve months of 1908, one may easily discern that the mining industry in south-eastern British Columbia has progressed. The year dawned upon a dark outlook; the copper mines of the Boundary were closed down; there were rumors that the Le Roi mine, at Rossland, would stop work; furthermore, the probability of the Dominion lead bounty ceasing in June did not encourage the owners of low-grade lead-silver mines. The work of the Granby Consolidated in the Boundary district, however, cast a ray of light over the situation, and the slight rise in the prices of metals gave hope for much better conditions during the forthcoming months. The Granby company in January was working but half of its regular force, but week after week the ore shipments were augmented, until during the week ending March 22 a record of 27,288 tons was made. While shipments have fluctuated to some extent, the Granby ore production has been steady, and the output for this year will exceed that of 1907 by 400,000 tons. This company has expended \$200,000 in improvements in its mining, smelting, and converter plant, and is prepared for a heavy output during the coming year. Following the lead of the Granby, the B. C. Copper Co. resumed work at its mines early in the year, and, after putting in new ore-crushing, air-compressing, and smelter machinery, shipments were begun to the Greenwood smelter in May. The output of the B. C. Copper Co.'s Mother Lode mine this year shows an increase of 100,000 tons, while the shipments made by the Oro Denoro will offset the ore shipped from the Emma last year and exceed it by 65,000 tons. The heavy fixed charges, economical method of mining and smelting, and the general adjustment of conditions making it advisable for the two principal concerns of the Boundary to resume work, it naturally followed that the Dominion Copper Co. should fall into line. In June this company resumed operations at its mines, and a few weeks later blew in the large modern furnace at the Boundary Falls smelter, resuming shipments to that point. The coke shortage, subsequent to the Fernie fire, caused the Dominion Copper Co. to stop work at

both mines and smelter. It became known that the company was short of money. Mining was resumed in an effort to keep things moving, but, money not being forthcoming to pay the miners' wages, work was suspended, and a little later on the affairs of the company were carried to the courts. Re-organization is now under way. With the exception of this company, the Boundary mines have made notable headway. The Consolidated Co. opened up the Snowshoe mine in August and began shipments to the Trail smelter in September; in November, there being a surplus of ore at Trail, this surplus was treated at the Greenwood smelter of the B. C. Copper Co. A compressor plant was installed by the same company on the Phoenix Amalgamated property, where active development has disclosed a good body of ore, somewhat resembling that found in the Granby mines which are situated adjacent to it.

The plan of work outlined by W. A. Carlyle for the Le Roi is giving good results, and the mine will show a profit this year, even though the shipments will be about 35,000 tons less than in 1907. The ore sent to the Northport smelter has been of a better grade than last year. The profit won by the Le Roi was greatest in October, when \$50,000 was earned. Work on the Centre Star, War Eagle, Iron Mask, Idaho, and Enterprise claims of the Consolidated Co. has given gratifying results; in consequence, the shipments for 1908 will exceed 1907 by over 50,000 tons, and the profits will be proportionally larger. The property has been earning an average of \$35,000 or more per month. Two good strikes were made at the Le Roi No. 2 during the year, and that the company has made money is shown by the payment of \$1.44 per share in dividends. The development work on the Giant-California has not yet resulted in the finding of ore-shoots. While the Jumbo and White Bear have remained idle, it is expected that money will be available to start operations on these properties early in 1909.

At Nelson, the Silver King mine is once more active. The Queen and Nugget, on Sheep creek, have attracted attention by their profits. Continuance of the lead bounty has stimulated work among the small mines of the Slocan, and the showing this year will be better than for 1907, although the total shipments will show a decrease. This decrease is caused by the inactivity of the Sullivan, La Plata, and other heavy producers of low-grade ore. The Blue Bell mine has been improved to the extent of \$200,000 during the year, and can now mine and treat a heavy tonnage of low-grade ore, of which there is a large quantity on the ground. The St. Eugene mine, at Moyie, has shipped 2000 tons more than in 1907, and there is a good lot of ore ready for stoping in the upper levels.

Taking everything into consideration, the local mining industry has improved. The Rossland output will exceed that of 1907 by 10,000 tons, despite the drop in Le Roi shipments; the Boundary tonnage will surpass that of 1907 by over 290,000 tons. The mines are prepared for a heavy output during 1909, and now that the financial trouble and other disturbing factors have been adjusted, a prosperous future seems assured.

SANTA EULALIA MINES, CHIHUAHUA.

Written for the MINING AND SCIENTIFIC PRESS
By F. J. H. MERRILL.

This important group of mines is situated 17 miles southeast from the city of Chihuahua, on a mountain area about eight miles in extent from north to south and six miles from east to west.

It is traditional that the mineral deposits of Santa Eulalia were worked by the natives before the Spanish invasion; but they were discovered by the Spaniards about 1591 and first opened about 1703. Official records tell us that the older mines of the camp: the Vieja, Aguada, Santa Rita, Santo Domingo, Parcionera, San José, Dolores, and others, yielded an immense tonnage of rich silver ore; this was smelted in primitive adobe furnaces at Santa Eulalia and also at the city of Chihuahua, which owed its early development to these important mines, and at one time supported a population of 70,000, since shrunk to 40,000.

Kimball quotes government records showing a production from 1705 to 1791 of 11,903,126 mares, or 95,225,008 Spanish ounces, equivalent to nearly \$112,000,000; and he estimates the entire production at one-fifth to one-half more than that reported to the tax collectors. The district supported a population of 6000, with 63 reduction establishments, besides several furnaces at Chihuahua. From 1795 to 1800 this region was ravaged by hostile Apaches, and the camp was gradually abandoned. In 1810 began the revolution against Spain, which lasted 11 years, during which Mexican mining generally was at a standstill.

The ore, in the early days, was mainly taken from immense caves, one in the Parcionera, now closed by settling of the ground, being large enough to hold the Chihuahua cathedral. An important feature of these caves was that they afforded storage for the small amount of waste rock that was broken down; so that the oldest openings show no dumps. An additional economy, in connection with the methods then in use, was that some of the old water-channels could, with little labor, be shaped into inclined planes, up which the ore might be carried from the lowest workings on the backs of peons, or even on burros or mules. It is claimed that some of the oldest workings, which were probably operated by natives before the Spanish invasion, were in the southeastern part of the area near the claims now known as La Carlota and El Chiribel. Here the ores contain some gold. It is needless to remark that the mining of those days was on rich ore from the very surface. The first profitable discoveries were on rich shoots or chimneys exposed at the surface, and leading down to connect with the great cave-deposits that made the fortunes of the early mine-owners. These paid so large a revenue to the Government that the cathedral at Chihuahua, which cost \$800,000, is said to have been built entirely with the tax money of 1 real (equal to 12½c.) per marc (8 oz.) of silver paid by the mines of Santa Eulalia.

The Santa Eulalia mountain area consists geologically of two principal formations. The lower is

Cretaceous limestone, of which about 500 ft. is exposed in canyon erosion and some 2000 ft. has been cut in the mine-workings. The upper is a clastic deposit, partly limestone-conglomerate and partly volcanic breccia and tuff with thin sheets of lava. This has hitherto been generally classed as volcanic, but the base is of sedimentary origin. The limestone is elevated above the surrounding country in the form of a boss or dome of which the central axis, according to Kimball, is near the Vieja property, and from this axis the rock dips in all directions, beginning near the axis with an angle of about 5°, increasing to 30° and even to 45° on the outer slopes. This brings the limestone below the breccia at the valley-bottom in Santa Eulalia village; on the lower slopes of the mountain no limestone has been seen.

The mountain is deeply channeled by erosion and the ravines show many vertical escarpments, which are evidently due to extensive faulting of the limestone, the fault-planes then being worn down by the

Showing Position of Santa Eulalia.

drainage. While some writers have commented on the absence of faulting here, the evidence of a 700-ft. displacement in a faulted block near the Zubiate property seems conclusive, and one observer states that he has seen proof of a displacement of 1100 ft. This matter is of importance in its bearing on the interruption and displacement that would occur in the ore-bearing zones and orebodies in the faulting was subsequent to the mineralization. I have not yet observed any evidence on this point.

The upper part of the limestone exposed in the Democracia shaft is a coarse conglomerate, with calcareous cement, but, in freshly blasted surfaces close scrutiny is necessary to detect the real character of this rock. Following down the ravine that leads past the Inglaterra property to the village of Santa Eulalia, in the low ground, the conglomerate is well exposed, the boulders, which vary from 3 in. to 3 ft. diam., weathering conspicuously. This conglomerate is composed of water-worn material, and is a true sub-aqueous sediment, although volcanic action was taking place during the deposition of its upper portion.

The base of the conglomerate passes gradually

into the bedded limestone from which its boulders were derived, with the re-crystallized dust that cemented them. On the ridge above the Inglaterra and Democracia properties and elsewhere, the upper part of the limestone conglomerate has for its cement a paste of volcanic rock-dust. This conglomerate was not seen on the high ground near the Santo Domingo mine, and further study may show that it is limited in extent, and was formed as a beach-deposit on the flank of the Santa Eulalia uplift when this lay as an island in the surrounding waters. Above the conglomerate and, where it is lacking, resting on the bedded limestone, are extensive deposits of tuff and volcanic breccia, about 300 ft. thick, called by the Mexicans *cantera*, and by some Americans 'porphyry capping'. Intercalated with the breccia at some points, or cutting it horizontally, are thin sheets of lava. The breccia and conglomerate form a deposit that is seen at many points in northern Mexico resting unconformably on Cretaceous strata. The few hundred feet exposed at Santa Eulalia are probably only a fraction of the original thickness, which at Sierra Mojada is estimated at 1800 ft. Some of the Sonora conglomerates have been described by E. T. Dumble under the name of Baucari, Nogales, and Trincheras beds. The Baucari beds were observed in the district of Alamos, and the Nogales and Trincheras beds in northern Arizpe, near the Arizona boundary, but strata comparable lithologically to the Nogales beds are widely developed along the Yaqui river from Buena Vista to Tonichi. I called attention to a quartz-porphry conglomerate, passing into a red sandstone of wide extent, at Planchas de Plata in the northern part of the Magdalena district, Sonora, and extensive beds of conglomerate form the summits of some mountain peaks in the Copete mining region of the Ures district of Sonora. Other conglomerates have been observed on the mountains near the La Brisca placers at Magdalena. If these conglomerates were shown to be limited to small areas, they might be regarded as lake deposits, but insufficient geologic field-work has been done in Sonora to prove their areal limits, and the possibility of marine submergence of this area during deposition cannot be denied with certainty.

The limestone encloses the main orebodies, the breccia being, so far as known, entirely barren except for small stringers of ore in narrow fissures. It appears, therefore, that while the mineralization occurred subsequent to the volcanic action that resulted in the deposition of the breccia, the precipitation of the metals was essentially confined to the soluble limestone. The ore occurs almost wholly in caves and chambers, in close association with old water-channels, though it is evident that these caves and channels were formed by subterranean drainage from the surface, subsequent to the mineralization of the limestone along its fissures, and contemporaneously with the oxidation and alteration of the metallic sulphides with which the limestone was primarily impregnated, and by which it was in part replaced. The original ore deposits were replacements of the limestone, chiefly by galena carrying

silver, the sulphide of lead having subsequently been oxidized and altered to the carbonate, or cerussite. In some mines pyrite is found, together with calamine and smithsonite as alteration products from sphalerite. Zinc ores are said to occur in the mine El Potosí at a depth of 1600 ft. The oxidation of the larger masses of ore extends as far as the lowest workings, but occasional nuclei and stringers of galena may still be seen. The native miners identify two principal classes of deposits at *mantas* and *abras*, the former being approximately horizontal sheets of ore replacing soluble layers of limestone, and the latter representing replacements along the walls of nearly vertical fissures. These phases obviously pass into one another.

Philip Argall notes that the great caves, water-courses, and ore deposits occur along certain main fissures that have a general northerly direction, and are usually situated at points where the main fissures are intersected by cross-fractures. As the development of the district is extended it will be of interest to observe how far this generalization proves correct for the whole area. The wide and deep fissure of the Zubiato property, in which are said to have been large orebodies, has a strike at the surface of about N.70°E. magnetic. Mr. Argall also makes an observation that is of importance if generally true, namely, that in the process of oxidation the lead and silver were leached from the upper deposits to the lower, so that the ore in caves at higher levels is lean and limited in volume, while in the deep mines the caves are full of rich ore. This may be true of a number of properties, but tradition tells us that when the region was first exploited rich ore was followed from the soil downward.

Numerous dikes and sills of eruptive rock occur in the district, some of which were noticed near the Zubiato property, but whether all are of one variety has not been determined. In the southeastern part of the district they are abundant, and in the San Antonio property, orebodies are found at the contact of the limestone with a porphyry intrusion. These contact deposits are said to continue across the Enriqueta into the Carlota. The workings in the El Potosí mine have attained a depth of nearly 1800 ft., and it is said that in this part of the district most of the large orebodies opened within the past few years are below 1000 ft. When and where the downward limit of secondary enrichment will be found is a question of great interest.

In the early days of the district, many bonanzas were found containing chloride and sulphide of silver, and some are found still, but the output now is of moderate grade, probably not exceeding an average of 20 oz. silver for the better class of ores, and there is a considerable tonnage assaying as low as 6 oz. per ton. The lead content is said to average below 25%, with considerable amounts of iron and alumina. These ores, though relatively low in grade, are of special value to the smelters for their fluxing qualities. As far back as 1867 Lew Wallace wrote that the Santo Domingo and Dolores ores were chiefly valued as fluxes.

The discovery of ore at Santa Eulalia is often a

matter of chance. In the beginning ore was followed from outcrops in the limestone, and from the caves entered in the progress of this work 'leaders' were traced laterally into other chambers, the position of which was a matter of speculation. But the general richness and extent of the mineralization amply justified the search. The so-called 'leaders' are narrow fissures in the limestone filled with ferruginous argillaceous matter, which contain traces of lead, but rarely any important amount of silver. In following these fissures, small cavities and water-channels are frequently cut; these, in themselves, are of no value but suggest the existence of larger channels and caves in the neighborhood.

As the district attracted attention, and the ground on which limestone was exposed at the surface was located by 'denouncement', it was necessary in seeking new deposits to sink through the 'porphyry cap-

the facts have not been made public. In faulted ground, moreover, the displacement of ore-bearing horizons may lead to unexpected expense in finding ore.

The present condition of Santa Eulalia is eminently one of prosperity. In spite of some failures, there are many successes. Whether the ore be high-grade and valuable for its silver content, or low-grade and esteemed for fluxing, it appears to find a ready market. Transportation facilities are excellent. The Chihuahua Mining Co. operates a railway from the outskirts of Chihuahua into the northern and central portions of the district, handling the output of the Santo Domingo, El Potosí, and other mines. The San Toy Mining Co., operating the Galdeano and other properties, transports its ore by a wire-rope tramway to a branch of the Ferrocarril Mineral. The newer mines of the eastern part of

Mexican Miners at Work.

ping' or beds of breccia. Shafts thus sunk were continued until ore was found or promising leaders were discovered, the latter being followed by drifts, winzes, or raises until an orebody was opened. The practice in this respect at Santa Eulalia is similar to that at Sierra Mojada, where sometimes a leader has been followed 300 metres in the search for ore before success rewarded the miner's effort. It is obvious that in a limestone, irregularly impregnated, a shaft may easily miss an orebody. Lateral exploration must then be resorted to. It is obvious that in ground like that of Santa Eulalia exploration should be backed by ample capital, and continued with rigid economy, as no one can estimate beforehand the cost of finding ore. This is exemplified in the Baltimore property, where a shaft was sunk 1300 ft. without finding ore, although numerous leaders were intersected. Similar conditions doubtless exist in many prospect shafts, concerning which

the district have no railroad connection, but busy strings of burros carrying sacks of ore to the station at Santa Eulalia give proof of productivity. The transportation rates to El Paso are favorable for the shipment of low-grade ore, though some of this goes to the smelter at Torreon. Only a few miles from the camp, on the plain toward Chihuahua, is the new Guggenheim smelter. Labor commands about the same price as at other large camps in Chihuahua, though contractors have learned to make better profits. For sinking shafts less than 500 ft. deep \$50 per metre is a regular price. For depths greater than 500 ft. \$70 per metre is usual. To this should be added about \$30 per metre for expenses of hoisting, blacksmith work, and incidentals. Mine-timber costs about \$60 per M. board measure, delivered on the ground. A point of advantage at Santa Eulalia is that the mines are generally dry, so that little expense is incurred for handling water.

ore being \$3.62. The average total cost of mining and milling, including management and depreciation, varies from \$2 to \$3 per ton, and it is claimed that the total cost in the Melones mine is below \$2 per ton. Nearly all the mines are worked through shafts, a prominent exception being the Melones, the main adit of which starts near the Stanislaus river and extends north to a point under the crest of Carson hill. Electric power generated by water and direct water-power are mostly in use, but both wood and oil are also employed to generate steam. The ore is usually soft, allowing a high duty, often 4 tons per stamp per 24 hours. The soft slate walls and wide veins cause the bills for timber to run high, frequently 35c. to 40c. per ton of ore extracted. Square timbers are used and also the local digger pine. In general, all mining supplies are cheap and labor is low, \$2.50 to \$3 per shift.

During 1908 work has been going on at the Bunker Hill, Bay State, Keystone, Fremont, Oneida, South Eureka, Central Eureka, Argonaut, Kennedy, Zeile, and Amador Queen in Amador county; at the Gwin,

Kennedy Mine, California.

Lightner, Etna-King, Utica, Gold Cliff, Angels, Bruner, Chaparral Hill, Finnegan, and Melones mines in Calaveras county; in the Tarantula, Harvard, App, Jumper, and Eagle-Shawmut mines in Tuolumne county; and at the Josephine, Princeton, and Mariposa mines in Mariposa county. There has also been activity at the Mack mine at Big Oak Flat, but this is not strictly on the Mother Lode.

Exploration to the depth of over 1400 ft. in the large mines on the Mariposa grant seems to indicate that while the veins remain strong, the gold decreases with depth; but with the Gwin, Kennedy, and many other mines the ore has not become impoverished with depth, although, of course, the costs have increased. The Gwin has good ore on the 2400-ft. level and even deeper, and the Kennedy is said to have good ore 3000 ft. vertically below the surface. The Eagle-Shawmut is down 2600 ft. and better ore is reported on the lower levels than above, although heavy in sulphides. In the chlorination plant at this mine there are two roasting furnaces—a 20-ton Hall, and a 10-ton Edwards. Oil fuel is used. The mill is run by water-power, and has 100 stamps of 1000 lb. each, and 40 Frue vanners. During the year over 1000 stamps have been dropping on the Mother Lode, but many mills were closed down from lack of water in the late summer and early fall months.

CRIPPLE CREEK IN 1908.

Written for the MINING AND SCIENTIFIC PRESS
By W. W. TRAVELL.

It must be admitted that the Portland mine now stands as the Independence did some four years ago, when the consulting engineers to that company advised the London office to introduce the leasing system—that is, the Portland is very much of a shell. Its main orebodies, like those of the Independence, are worked out, the average grade of the ore cannot be much more than \$16 per ton, and, although the Portland company has its own mill at Colorado City, the profits must necessarily be small, owing to the great amount of waste, large expense of timbering, long tramming distances, and the very low grade of the ore. One must not, however, lose sight of the fact that in this mine the line of contact with the

A Part of Colorado.

granite, pitching as it does from the Independence north end into the Portland, will give pay-ore at a much greater depth than in the Independence. On the latter property Mr. Hammond carried the shaft down to the 1400-ft. level, and did much driving and cross-cutting at that depth, without finding any ore better than \$3 or \$4 per ton. The pay-ore below 1100 ft. seems to have been cut off at the contact. The Portland may continue to do fairly well a little deeper than this, although, as before stated, the ore seems, on Battle Mtn., to become poorer in depth. The company undoubtedly has a valuable asset in the dumps; these cannot be less than 1,500,000 tons, and remembering the fact that the Portland company, for years, never leased or washed the dumps, the average value of the whole should not be less than \$4 per ton. This is a considerable item. It is known that the company has been experimenting on the dump ore for some time at Colorado City, and is now erecting a small plant (10 stamp mill) near the mine.

They are proceeding carefully, spending probably not more than \$15,000 on the outfit. The method will be to convey the ore automatically to the mill for crushing, pass it over concentrating tables, and then cyanide. The tailing will be put over a second table. It is reported that they are going to very little expense in the matter and are obtaining the most up-to-date tables; by reason of many years of experience in milling their oxidized ores at Colorado City they should be able to devise the best and cheapest means for treating the dumps. It would seem wise, judging by the experience of the Stratton's Independence company, to lease the upper levels of the property, instructing their superintendent to watch the timbering and attend to the general supervision of the lessees. Twenty or thirty sets of brains are better than one in following and discovering ore, and should the Portland company decide to lease the upper workings, I believe their experience would be even more gratifying than that of the Independence, which, after losing some \$50,000 in one year on company account, made a profit next year of \$1,000,000—the mine making \$500,000 and the lessees, \$500,000.

Four years ago the Stratton's Independence mine reached the condition in which I have described the Portland to be, and the consulting engineer wisely decided that the time for leasing had come. His good judgment was only too well proved by the splendid results, both to the lessees and company, since then. Certainly not less than a million dollars had been made by the company, and a similar amount by the lessees during that time. There was much unfair criticism by the press and public regarding supposed exorbitant charges for royalty, hoisting, air, etc., but time proved that such was not the case; the lessees made an almost equal profit with the company. It is common knowledge that a lessee can and does work 30% cheaper than a company, to say nothing of having some 30 or 40 alert miners looking for ore. So that when a large mine like the Portland or Independence finds its main orebodies exhausted, with nothing but small stringers, an occasional pocket to find, and mainly development work to do, it is well to lease the workings. The Independence is now in its secondary stage, that is, where the lessees have practically cleaned out all the pay-ore, although there are still some fourteen sets of lessees making a little money for themselves, and a little for the company. It has been deemed wise to make a further change. There are many thousands of tons of ore running from \$5 to \$10 per ton in the mine, and undoubtedly much of better value would be exposed if a system of caving were adopted, for whenever caves have occurred in the mine good ore has been opened up. Experiments having shown that refractory ores of low grades can be mined and milled at a profit, the management decided to build a mill for this purpose. Moreover, after being most thoroughly sampled by George A. Schroter, who put down some 25 shafts all over it, taking waste and ore just as it came from the shafts and crushing and sampling it, and reducing all assays to \$6 per ton, the dump showed an average value of \$3.75 per ton. Some 700,000 tons of ore averaging not less than \$4

per ton must be on these dumps, and Philip Argall, who has spent some \$300,000 on an elaborate mill, will now have an opportunity to show what can be done toward the successful treatment of this immense tonnage. From the data given by Mr. Argall, his cost of extraction should not exceed \$2.75 per ton, so that if Mr. Schroter's figures are correct (and we have every reason to believe that they are) this would leave a net profit on the dump alone of about \$700,000. As we understand that the company in London has, under a re-organization scheme, raised the necessary funds to pay off all machinery and other debts, leaving a handsome sum on hand to enable Mr. Argall to push his tests to completion, we may reasonably hope to hear of definite results within the next two months. Should the mill prove to be a success it will mean much for Cripple Creek, as there are immense tonnages of low-grade ore in most of the larger mines, and many of the smaller ones, and it will give a stimulus to the camp for many years, besides increasing the possibilities of opening up higher-grade ore while working on the poor stuff.

The Golden Cycle mine has been one of the steadiest and largest producers in the camp for many years, and the great help given to the Cripple Creek district by J. T. Milliken in building an 800-ton mill at Colorado City and treating (in addition to the Golden Cycle ore) custom ore, cannot be over-estimated. Their rate of \$4.50 for freight and treatment on \$8 ore was the means of making the camp look like 'old times' again, for almost every property with anything in sight, commenced operations either under lease or company account, and everyone was looking for leases in the mines or on the dumps. The United States Reduction & Refining Co., to meet this competition, put down their rates even lower than the Golden Cycle, making a \$3.50 rate on \$8 ore (though they have since raised this twice during the last three months), thus more than ever stimulating development work all over the district. Unfortunately many lessees shipped thousands of tons of dump ore that ran close to \$4, leaving the Reduction company but little margin for loss, hence their reasons for putting up their rates to discourage the shipment of ore running under \$10 per ton. However, the good work done by the Cycle people is highly commendable, and has been the means of bringing the camp back to a good monthly tonnage. The Cycle property is now working at a depth close to 1400 ft. and yields about 150 tons per day of ore averaging close to an ounce. This mine differs from the Portland and Independence in that much of its better grade of ore is found in the lower levels, having immense bodies of its highest-grade ore at 1200, 1300, and 1400 ft. I consider the Cycle good for a tonnage of 150 per day of ounce ore for many years, with great possibilities in their lower levels. The ownership of reduction works is a feature that will enable this company to continue production when their ore becomes much lower in grade.

The Elkton mine is producing about 2000 tons per month of good-grade ore, probably an average of \$25 per ton. I consider the Elkton one of the best properties in the Cripple Creek district, with possibili-

ties of a long life. Large bodies of ore of grade better than an ounce exist at the lower levels. At 900 ft. (just about water-level) an excellent showing is being developed, and with the completion of the drainage adit large bodies of high-grade ore will be exposed that have been covered during the last few years since pumping operations on the lower levels ceased. A large tonnage of good-grade ore will undoubtedly be shipped from this property for many years. The Cresson mine is also steadily yielding ore averaging close to an ounce. At present some development work is being done, so that the tonnage is not as large as usual, being in the neighborhood of 1500 tons per month. The Dante, Trilby, Blue Bird, Gold Sovereign, and their neighbors have excellent showings and are making a fair output. The Dante is the best of these, producing about a car per day of ore averaging \$20 per ton. The Isabella is not doing quite as much as usual, but the cyanide mill seems to be successful with the dump ore, and as this property from the 100 to 700 ft. is in the oxidized zone, there should be no trouble in treating many thousands of tons of ore too low to send to the reduction works.

Work is progressing satisfactorily on the drainage adit, some 4000 ft. having been driven, and an average of about 12 ft. per day is being maintained. With the completion of the adit, the El Paso, Elkton, Portland, Strong, and many other properties will undoubtedly be greatly benefited, so that, taken as a whole, the camp should be a producer for many years yet of, say, some 40,000 or 50,000 tons per month of ore of an average grade of \$15 to \$20 per ton.

The Vindicator mine has been one of the large producers of the camp and, at present, is worked almost entirely by lessees. Some of the richest ore found in Cripple Creek has been taken from this property, and many of the lessees have done exceptionally well. I consider it will be a steady shipper for many years yet, with possibilities of opening up additional orebodies under the leasing system. The main ore-shoots have been worked out, but much good territory remains undeveloped. A steel shaft-house and head-frame 80 ft. high are being constructed at the No. 1 shaft, showing the company's confidence in the continued finding of ore. At present they are making an average production of about 1600 tons per month, and four dividends, amounting to \$45,000 each, have been paid since the first of the year.

About the beginning of 1908 the El Paso Gold Mining Co. decided to lease its upper workings, which showed little or no profit under company management, pending the completion of the new drainage adit. Their good judgment has been proved by the majority of the lessees doing well and paying the company fair royalties. This one mine should become one of the most active producers when the drainage adit is completed, as undoubtedly large bodies of good-grade ore exist in the lower workings.

The Strong mine is one of the steady producers of the district, the ore being almost entirely in the granite, near the contact. There is good ore at depth,

and I anticipate production for many years. Several million dollars have been paid to the owners during the past ten years; it is a close corporation, having only three or four owners. Their present output should not be less than 2500 tons per month of \$30 ore. During the period that the Gold Coin mine, now called the Granite, was owned by the Woods family it produced many million dollars worth of ore. It is, however, practically worked out and, although a few sets of lessees are working, their output is small, and I do not anticipate much from this property, until perhaps such time as the mills can treat the very low-grade ores at a profit. Although during the past twelve months the output from the Findlay has not been large, I understand that reserves are stored in the stopes and in the lower levels (1200 ft.) good ore is said to exist. Under vigorous management and development work the Findlay should be a steady producer for many years. The Hull City Placer main workings are merely a shell, but with territory well located and not yet tested. This mine is under lease entirely and will probably produce a fair tonnage for several years.

The Mary McKinney, one of the old mines, is now under lease to the Western Investment Co., which has sub-leased to several sets of lessees. A fair tonnage of moderate grade is being shipped and with the development work now under way, this property should continue to maintain a steady output. The Doctor Jack Pot, Work, and adjoining properties are producing, chiefly under lease, with prospects of continuation.

The entire Stratton Estate properties, such as the American Eagles, Lucky Gus, Specimen, Sacramento, are under lease and many of them are productive. Several new orebodies have been discovered on the American Eagles. The Lucky Gus, under lease to H. G. Moore and associates, has been one of the best operations in the camp, having paid each of the three lessees some \$50,000 during the year, and they are still making a good production of high-grade ore. Generally speaking, with the necessary development, the properties of this estate should produce a fair tonnage during the next five years.

The platinum output of Colombia is second only to that of Russia. This precious metal, washed from the gravels of the Chocó, is found associated with gold, the platinum, however, predominating. Although platinum occurs to some extent in other parts of the Chocó, the main sources are the Platina and Condota rivers, and a few tributaries, as well as the streams running into the Cajon, all being affluents of the San Juan river. The metal is also obtained from the Agua Clara river and portions of the Bebera river, both of which flow into the river Atrato; it is obtained also from the Cartegui, the main affluent of the Quito river. Though platinum occurs in the wide areas of the Chocó in the stream beds, and on the banks bordering the San Juan valley, it has not yet been found in veins. It seems to be a re-concentration from older gravels, deposited apparently in the Tertiary age.

COAL MINING IN CHINA.

Written for the MINING AND SCIENTIFIC PRESS
By THOMAS T. READ.

Mining interest in China is at present chiefly centred in coal. Indeed, this is likely to remain permanently the case, for in the list of the mineral resources of China coal easily takes first place. The present output of coal, something like 15,000,000 tons per year, probably exceeds in value all the metallic products combined.

The principal coalfields of China fall into three large groups. First and most important is the North China field, an aggregation of smaller areas. In various places in the provinces of Shantung, Chili, and Shansi, and also in Manchuria, valuable coal seams outcrop and are more or less actively worked. The larger part of the total production at present comes from these fields. Their detailed description will be given later on. The second, or southern field, centres about the southern part of the province of Hunan. One large mine is here worked by foreign methods, and there is also a large production from native mines. The third, or western field, is in the basin of the Ssu-chuan. I have not visited this field, and can only cite Von Richthofen,¹ who says, in substance, that coal is very generally worked throughout the province, the Mesozoic strata being extensively folded and cut across by rivers, thus conveniently exposing the seams for the native method of working. The coal is not of so good quality as that of the southern field, so it is not shipped down the Yang-tze to compete with other coals in the markets of the lower river. The difficulties of navigation on the upper Yang-tze undoubtedly have much to do with this, as well as its quality. In the northern and western part of the province the quality is better. A foreign company has secured a concession at Wanh-sien and has installed foreign machinery, but I do not know how much they are producing at present.

In the southern field the chief producer is the P'ing-hsiang colliery, owned and operated by the Han-Yang Iron Works. This mine is in the province of Kiang-si, just on the borders of Hunan, and on the northeastern border of the field. At present it has a production of something over a half million tons per year, but this is steadily being increased, the limiting factor being the transportation on the Hsiang river, which is very shallow during a large part of the year. About three-quarters of the coal is made into coke at the mine, where there are six modern retort batteries, or 154 retorts in all. The remainder is shipped as lump coal to Hankow for the use of the iron works and for sale in the open market. There are two washing plants for washing the coal before coking. Electric haulage is employed underground, this being the only mine in China employing electric haulage. There are many native mines worked in the vicinity. Coke is also made in native ovens. A missionary writer speaking of coal in China has gravely said that the Chinese make their coal into coke because the coke is lighter and hence easier to

transport. The real explanation is that the coals are generally so friable that they will not bear transportation. From this point the coalfields extend south and west over a large area, and are worked in many places by the natives. Von Richthofen says that the coal becomes anthracite toward the south and is of much better quality, but because of the transportation difficulties development has lagged. When the Canton-Hankow railroad is finally in operation this portion of the field should also become important. It is impossible to estimate the amount now produced in this district.

There are numerous companies under foreign supervision in the northern field. Of these the oldest, largest, and best known is the Chinese Engineering & Mining Co., which operates at Tongshan and Linsi, in northeastern Chili. The total production is fairly constant at about a million tons per year. The mines are well equipped with modern machinery; a 3000-kw. electric plant for hoisting underground, pumping, and for lighting having just been installed at the Tongshan mines, and a similar plant at Linsi. Another mine is about to be opened with Chinese capital, about half-way between these two mines. The work at this mine was fully described by Hoover² a few years ago.

In Shantung there are several fields. The Schantung Bergbau Gesellschaft is operating mines at two places, Po-shan and Fank-tze, and produces about 200,000 tons per year; native workings in the vicinity produce an indeterminate amount. The coal from the German mines is washed before being sold. The fields are not large, and the coal is not of the best quality.

Farther to the southeast, near Yi-hsien, there is a larger and better field. Coal is worked here in native mines, and a short line of railroad is now being built to connect the producing district with the Grand canal, and will doubtless also connect with the Tientsin-Pukow railroad when the latter is finished. The short line should be in operation within a year, and the Tientsin-Pukow line is now under construction. Modern methods will be introduced with the advent of the railroad, and this district should shortly become an important producer. The mines here are entirely in the hands of the Chinese, and I have not heard whether they are to be under foreign supervision.

The largest, most important, and least developed field in north China is the great anthracite field of Shansi, which has an extent of nearly 200 miles north and south and 25 to 30 miles east and west. Various writers have described this field as a whole, or in part, and these accounts have recently been summarized by Willis.³ The best account is that of Drake,⁴ who estimates the average thickness of the workable beds as 22 ft. Richthofen has estimated its area as 13,500 square miles, which corresponds to a total quantity of 350 billion tons in the whole field (Willis). The quality of the coal is excellent, as shown by the analyses, but, as is not uncommon with Chi-

¹Hoover, *Eng. and Min. Jour.*, August, 1902.

²*Economic Geology*, Vol. III, No. 1 (1908).

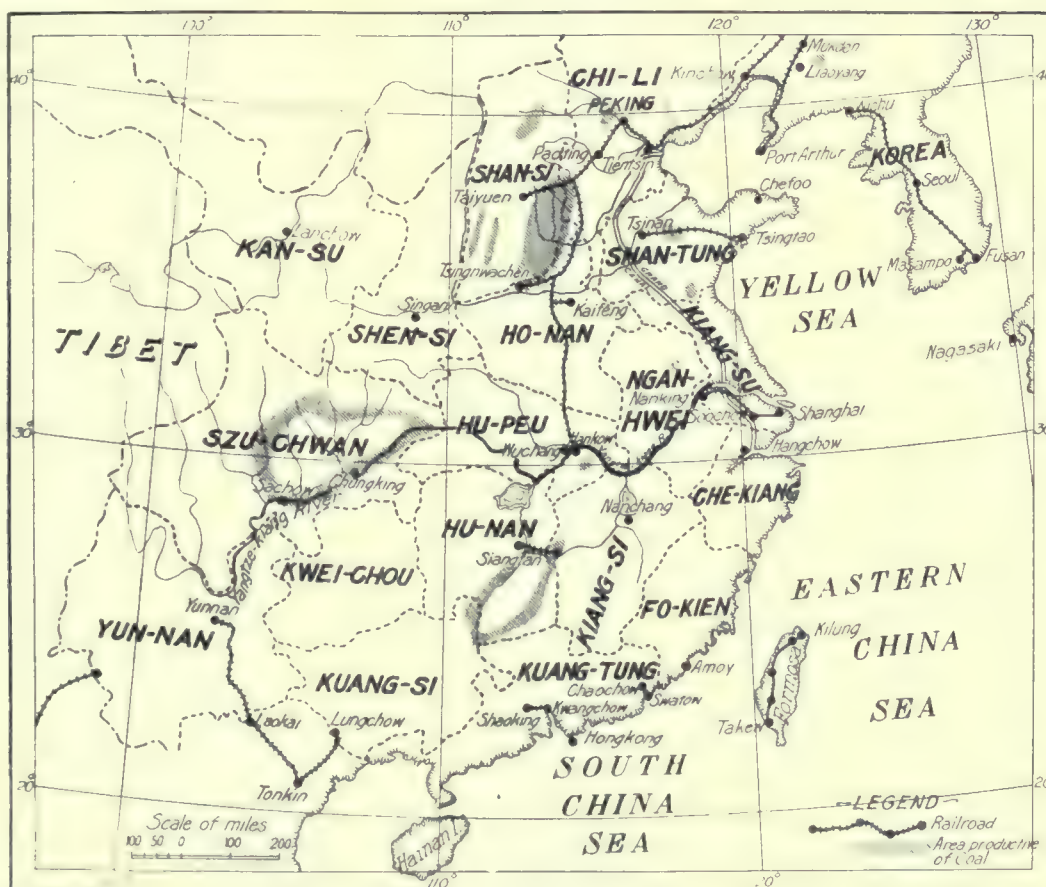

³*Trans. A. I. M. E.*, Vol. XXXI, p. 492 (1901).

⁴"Die Kohlenfelder Chinas", p. 177.

nese coals, the ash is rather high. In contrast to the coals from many other localities, it yields a very large percentage of lump coal. The lack of transportation facilities has been the restraining factor in preventing the development of the field. As yet it is only touched at three points by branch lines from the Peking-Hankow railroad. At the southeast edge of the field, in northwestern Honan, the Peking Syndicate has two shafts, but the work of exploitation does not seem to have been directed with a high degree of engineering skill, and the mines are only just beginning to make a small production after some years' work. The all-rail freight rates are so high that the company continued its branch line across to the banks of the Wei river, and from that point the coal goes in native boats down the river to the Grand canal, and thence to the ports.

of coal is produced by the natives, and there is one mine under foreign supervision at Ching-hsing (Ching-Ching). The working capital of this company has recently been increased and a German director appointed to act with the Chinese director, so the production will probably soon be largely increased. The high freight rates on these coals from the Shansi field makes them so expensive by the time they reach the ports that they are not used as much as their superior qualities might lead one to expect. The Imperial Railways are making such enormous profits that they could easily afford to stimulate the mining industry by lowering the freight rate, but apparently such a piece of foresight has not occurred to them.

Twenty miles or more west of Peking there is also a large production of anthracite coal from native mines, but none of these is using modern methods.

Map of China, Showing Coal Areas.

Somewhat farther north, in Chili province, are mines at Lincheng, from which the coal supply for the Peking-Hankow line is derived. These mines are only 10 to 12 miles distant from the main line, with which they are connected by a short branch. The mines are said to be worked under foreign supervision, and the production must be of considerable importance, as they supply the general market as well as the 750 miles of railroad, but I have not been able to obtain accurate details regarding them.

Still farther north, the northern edge of the field is tapped by a 160-mile branch line to Tai-yuan-fu, the capital of Shansi. This is a narrow-gauge road, and does not seem to be regarded with admiration by the foreigners who have been over it, who question its ability to handle any great amount of traffic. In the district tributary to this line a large amount

Drake⁴ has described this field in detail. Still farther north, near Kalgan, at Hwai-lai, the Peking-Kalgan railroad proposes to open a mine to supply its line with coal; this will probably be in operation within a year. West of the Shansi anthracite field is a bituminous field that Richthofen thought to be as large as the former, but the transportation difficulties practically remove this field from commercial consideration for the present. Farther west and north, coal is known to occur in various places.

attention, but the only available details regarding them are to be found in the reports of the Japan Geological Survey. The principal fields are at Saima-chi, Pen-su-hu, Wu-hu-tsui, and Yen-tai; the last The coal mines of Manchuria have attracted much

⁴Trans. A. I. M. E., Vol. XXXI, p. 492 (1901).

being the best known and most actively worked. The coal is anthracite, or semi-anthracite, rather high in ash, and very friable, so that only a small percentage of lump coal is obtained. All these mines are now completely under Japanese influence, and will be developed in the interest of the Japanese.

TABLE OF ANALYSES.

	Analysis No.				
	1.	2.	3.	4.	5.
	%	%	%	%	%

1. Tongshan Mines C. E. & M. Co. Average analysis, furnished by company.
2. Linsi Mines C. E. & M. Co. Average analysis, furnished by company.
3. Southern part of Shansi field. Average of 6 analyses by Shockley. *Trans. A. I. M. E., Vol. XXXIV, p. 840 (1904).*
4. Northern part of Shansi field. Average of 6 analyses by Drake. *Trans. A. I. M. E., Vol. XXXI, p. 492 (1901).*
5. P'ing-hsiang bituminous. Average analyses, furnished by company.

The foregoing table of analyses, gathered from various sources, illustrates the range of composition of the coal from the bituminous and anthracite areas of the northern field and the bituminous part of the southern field. Analyses 1, 2, and 5 are averages of a large number of daily determinations, and represent the average product with corresponding accuracy. Analysis 5 is of washed coal after drying. The coal as mined contains about 28% of ash. Analyses 3 and 4 are each averages of six analyses from different places in the same field, and may be taken as fairly representative. As may be seen from these, the coals are of excellent quality, except that the ash is at times undesirably high; the coal is generally of coking quality in the bituminous fields.

The accompanying map shows the general distribution of the coalfields. The map is taken from Richards' 'Geography of China', and in the areas assigned to the fields the map by Willis has been generally followed, although some necessary corrections have been made. The boundaries of all the fields are rather indefinite, as none of them have been studied in sufficient detail to fix their exact limits. In addition to the areas shown on the map, coal is known to occur in many other areas, Yun-nan, for example, but no attempt has been made to represent these, as the information regarding them is too indefinite. While the importance of individual fields has at times been overestimated by too sanguine observers, the estimates of the total coal resources of the Chinese Empire are generally below the amount available. It may be said that the coalfields of China have a large extent, the coal is generally of good quality, and the fields are widely scattered, so that it does not require to be transported any great distance from the points of production to reach every part of the empire. Nearly every coalfield is seriously handicapped by inadequate transportation facilities, but numerous railroads now building in different parts of the empire will soon provide markets and open the way to proper exploitation.

TAXATION OF MINING PROPERTY.

Written for the MINING AND SCIENTIFIC PRESS
By H. W. TURNER.

In the United States and its possessions generally, mining property is taxed in much the same way as other property; that is, the taxes are largely levied on the improvements.

In British Columbia, in the State of Nevada, and in Mexico, on the other hand, the chief taxes are levied on the product. This method is a distinct advantage to the mining industry, without decreasing the revenue from taxation. Mines that are producing can well afford to pay a reasonable tax, while those in the prospecting stage, or those that are temporarily shut down on account of low price of the product, or for other reasons, are not taxed, and hence debts are not piling up against them.

In British Columbia the method of taxing mining property is as follows: "Mineral or placer claims when Crown-granted are subject to a year of tax at 25c. per acre, but if \$200 is spent in work in a year this tax is not levied. A tax of 2% is levied quarterly on all ores and other mineral substances mined in the Province, based upon the net value of such ore at the mouth of the shaft or tunnel, but where ore-producing mines yield less than \$5000 in a year, half the tax is refunded, while placer or dredging mines that do not produce a gross value of \$2000 in a year are entitled to a refund of the whole tax. These taxes are in substitution for all taxes on the land, and for the personal property tax in respect of sums so produced, so long as the land is only used for mining purposes. By the 'Land Act' a royalty of 50c. per M, board measure, is levied on timber suitable for mining props, a cord of props being considered as 1000 ft. board measure."

In the State of Nevada, the mine tax law is as follows: "All the proceeds of mines, including ores, tailings, borax, soda, and mineral-bearing material, of whatever character, shall be assessed for purposes of taxation, for State and county purposes, quarterly, in the manner following: From the gross yield or value of all ores, tailing, borax, soda, or mineral-bearing material, or whatever character, there shall be deducted the actual cost of extracting said ores or mineral from the mine; the actual cost of saving said tailings, the actual cost of transportation to the place of reduction or sale, and the actual cost of reduction or sale and the remainder shall be assessed and taxed at the same rate, *ad valorem*, as other property is taxed."

There is no reason why a law based upon this principle should not be put into effect in California and other States. The attempt to deduct costs, in order to reach a net value of the output, is open to many objections. It encourages favoritism and falsification. The original draft of the basal mining law of the United States, prepared by Senator Sherman in 1866, contemplated a tax of 3% on the market value of the product. The change would seem desirable. It can, however, only be effected by the organized effort of the mining community.

PROGRESS IN CYANIDATION.

Written for the MINING AND SCIENTIFIC PRESS
By ALFRED JAMES.

Introductory.—In reviewing progress in this important branch of metallurgy, I venture to remind my fellow-workers that only by mutual co-operation can efficiency be maintained. One man can only hope to achieve a certain amount (let us term it x) of work, but 100 keen technical men putting their experiences together ought, by each proceeding from the other man's achievement instead of repeating the preliminary failures and troubles and costs necessary to attaining that position, to be able to accomplish something more nearly approaching 100 x . Let us realize what it means to make the same mistake only once, and proceed one step farther and realize what it would mean if the same mistake were made only once by one man out of the 100; then we can appreciate how even details of difficulties and failures are of value—it may be as examples of what to avoid—as well as triumphant records of difficulties smoothed out, losses eliminated, costs lowered, and extractions raised.

My notes of last year were necessarily hurried and cursory. They were written at sea, far from my records. Since then I have had an opportunity of visiting two of the greatest and most advanced mining regions, Mexico and South Africa. Such personal contact with local problems is of immense service, for the greater and wider an individual's experience the more he finds to learn.

Slime Processes.—Once more progress seems to have centred mainly in the production and treatment of slime. All-sliming may certainly be a moot question for certain ores, when the sands may be treated cheaply by percolation and do not yield a greatly higher extraction by total-sliming, but nevertheless all-sliming certainly seems to have 'come to stay,' as anyone cannot fail to believe who sees already scrapped the huge nearly new Blaisdell equipments at El Oro and Dos Estrellas; scrapped not for any fault of the apparatus, but because all-sliming with cyanide solution through the mortar-boxes has taken away the very reason for the existence of these labor-saving appliances. Anyone who has studied J. C. Butler's (Guanajuato) curves showing the amount of gold coming into solution in the battery against that dissolved in the sand-vats must find considerable food for thought; indeed, one is tempted to wonder whether the natural result of such a curve is not to indicate the desirability of abandoning the sand-plant entirely, delivering the pulp, properly prepared, into the slime-vats. Even in the chief gold-field of Mexico (El Oro) copper plates are already disappearing, but in spite of their having been ripped out at the El Oro and Dos Estrellas mills, the gold extraction obtained does not appear to have suffered either in cost or percentage, but rather the reverse.

As a result of the general inclination to sliming, increased attention has been given to means of fine crushing. Tube-mills have more than held their ground. We no longer hear of "pans *v.* tube-mill"

tests. Tube-mills are being installed almost everywhere with the exception of Australia and India. New types of mills have been advertised, but the old long cylindrical form still holds the field, with an established preference in big plants for a mill of from 4 ft. to 5 ft. 6 in. diam. by 19 to 22 ft. long. In the matter of certain tube-mill details, and of air-agitation, and of the wide-spread adoption of vacuum-filtration, Mexico has certainly been setting an example to the older cyanide regions, except New Zealand, which for the last two years seems to have led the way in tube-mill liners, air-agitation, and basket vacuum-filtration.

Other factors in Mexican practice are the large quantities of lime and lead acetate used for treatment purposes. It is a matter for serious question whether the use of lime is not carried to extremes, and whether some of the difficulties met with in the slime-treatment do not arise from an excess of lime. Thus at Guanajuato one of the companies feeds in 22 lb. of lime per ton of dry slime treated. At El Oro 15 lb. is used and at Dos Estrellas the practice is nearly the same. One of the results of this large consumption and solution of lime is the ever-present necessity of immersing the absorbent vacuum filter-leaves in dilute acid to restore their permeability.

Caldecott shows that lead acetate acts as a carrier, the eventual result being that the sulphur reacts on the cyanide to form sulpho-cyanide, leaving the PbO free for further action. I seem to remember investigating this matter in the laboratory some twenty years ago and coming to a somewhat opposite conclusion—based on the small amount of KCNS formed—but whereas in Australia very small quantities of lead acetate are used (say 2 lb. to a charge of 50 tons of roasted ore) in Mexico 16 lb. is used per ton of slime at Guanajuato, compared with $\frac{1}{2}$ lb. per ton at El Oro, where crushing to 25 to 30 mesh takes place, with heated 0.03% KCy solution passing through the battery. Contrary to the Caldecott equation, Mexican chemists state that the amount of lead salt required equals the corresponding amount of sulphur present in solution from the silver sulphide dissolved.

In central and south Mexico they are blessed with cheap power; effective horse-power costs from £10 per annum at one district, to 10d. per day in another—less than $\frac{1}{2}$ d. per hour. A feature of practice at El Oro is the provision of well-designed, roomy, neat extractor-houses which are better than those I have seen in any other part of the world. The extractor-boxes are raised some little distance above the main floor, which is cemented with drains running to a pump-sump. All precipitate is sieved through a 60-mesh screen, and thus 'shorts' are kept out of the bullion, and acid treatment is avoided. The shorts, or roughs, are placed on trays in a special extractor box and become fine at the next clean-up. Press precipitate is briquetted before fusion and makes a remarkably clean and neat product. Oil furnaces are in use, but tilting furnaces do not yet appear to have been adopted.

At Guanajuato large values have been carried

away in the slime-residue. During my visit residues containing 45 grams silver per ton, most of it in solution, were being run to waste down the creek. This does not mean that the men in charge were not keenly alive to what was being lost. The development of vacuum-filtration is recent, and though its spread has been remarkably rapid in Mexico it is not yet universally adopted. These residues when put through a Ridgway filter were impoverished to 13 grams silver, no dissolved silver remaining.

In Africa attention has been mainly devoted to lessening working costs, and the extraordinary spectacle is now presented of mines running at practically half of their former outlay, and of mines that are the richest as well as the largest in that territory, and in the world, running at working costs, including mining, handling, and treatment, of only 12s. per ton. In mechanical details there is still that keen rivalry between the two leading groups which has done so much for the advancement of the Rand. The 'Gold Fields' lead in their now universally adopted development of huge mills and heavy stamps. Already the output is stated to have grown to 9 tons per day per stamp (Luipaards Vlei, 'Gold Fields' group, 1650-lb. stamps) and the limit is not yet reached. The Simmer Deep mill of the same group has 1670-lb. stamps, capable of being weighted to 1800 lb., and it looks as though it would not be long before a falling weight of 2000 lb. will be reached. On the other hand the mechanical genius of the Rand Mines group has been evolving some interesting results on peripheral discharge with tube-mills, and has been displacing the wellnigh universally adopted tailing-wheel by centrifugal pumps of special design and local manufacture. Metallurgically the Gold Fields people have also done exceedingly well. Caldecott's forecasts of tube-mill results, as I have previously pointed out, were confirmed most remarkably in practice, and now he seems to be hard at work evolving a filtering process for the treatment of slime.

In Australia interest has centred on flotation processes for concentration, rather than on improvement in gold-ore treatment. Kalgoorlie seems to have reached its zenith, and to have settled down to steady practice. The treatment-costs given in detail in my review of 1906 still apparently hold good. The Ivanhoe costs for August, 1908, are 7s. 6d., as against 9s. in 1906, and those of the Great Boulder for the same periods are 11s. 6d., as against 11s., but, on the other hand, the other companies then mentioned—the South Kalgurli, the Great Fingall, and the Sons of Gwalia—show higher costs on the same basis. This reference to the Ivanhoe brings to mind the old controversies over roasting as against bromo-cyaniding (now dead), and pans as against tube-mills, in which this mine formerly figured prominently. It now appears, from local records, to have been at that time making particularly poor extractions—which tends to discount the low costs published—and a local metallurgist from Oroya-Brownhill, E. S. King, has recently sustained his claim at law for a large sum as recompense or fee for helping them out of their difficulties.

American practice seems linked with that of Mexico (largely controlled by Americans), and so the last year has been chiefly a chronicle of air-agitation and vacuum-filtration, as in Mexico, with much newspaper fulmination and advertising of rival filtration processes, and with the local success of the Merrill pressure-filter in South Dakota to offset the work of the Burt at El Oro.

Agitation. One of the features of the year has been the success of the Brown system of agitation, originally brought out at Komata, New Zealand, and adopted by the Waihi company. The latest and largest plants in Mexico and in the United States have adopted this system, which has now penetrated into Africa and South America. Daue has recently written a remarkable comparison in the *Mexican Mining Journal* for October, and shows at the San Francisco mill at Pachuca a consumption of only one twentieth of the horse-power used at the mechanically agitated Loreto mill, the Brown agitator showing considerably better extraction with a cheaper plant and giving a much shorter cycle of operation. The whole article is worthy of careful perusal. It seems abundantly proved that a charge of 80 tons (dry) of slime can be kept in a condition of efficient agitation for a consumption of $1\frac{1}{2}$ horse-power.

Much time has been spent in Mexico in endeavoring to improve the mechanical agitator by the use of footstep bearings with mercury seals and other devices, but the mercury seals in practice have proved unreliable and have manifested a considerable tendency to the formation of base amalgam, as one would anticipate from the behavior of this metal in amalgamating pans. Owing to the well known refractoriness of silver sulphide ores, the agitation periods are much longer in Mexico than elsewhere; indeed, 48 hours of mechanical agitation is not uncommon—a practical impossibility in any country where power is not extraordinarily cheap. Daue, in the article mentioned, shows that at Loreto the ore requires 84 hr. of agitation, whereas, with the same class of ore at the San Francisco, the period of agitation is reduced by the use of air-agitation to 24 hr., for a lessened cyanide consumption.

Vacuum-Filtration. Undoubtedly the feature of the year has been the success of vacuum-filtration. With such a combined host of talent as Nichols, Thompson, Moore, Barry, Ridgway, Brown, Nutter, Cassel, Butters, Hunt, Parrish, Argall, Ogle, Leslie, and Caldecott, and I know not how many others, vacuum-filtration could scarcely have failed to accomplish great things, and already five continents are eagerly investigating it with a view to adopting the practice in one form or another.

Even if we assume only 1,000,000 tons of slime handled by this process during the last year, it would still be a remarkable figure for a new method, but, on the data given, the Ridgway and Barry machines alone must have handled over half this amount, and therefore the total tonnage treated by the various methods, notably the Butters, must considerably exceed this. But in addition to the two methods first mentioned, the Butters filter can fairly claim to be a great factor in present-day practice. That it has

achieved this position is surely a tribute to the energy, push, skill, and remarkable engineering ingenuity of the man at the helm and of his associates. So attractive and so simple does the filter look that nothing seems easier than to run in the slime at one end, turn a handle, and have the pulp running away at the other end, with the gold solution pouring into the precipitation-boxes. Ridgway, in Australia, not content with the success of his flat-plate machine, has been trying to make a larger unit by substituting a basket for a flat plate, thereby largely increas-

Liberty Bell Mine.

ing his filtering area. I am not sure, however, of the soundness in practice of his later idea, of which one hears most laudatory accounts from disinterested sources in Australia. The principles governing the discharge of a flat-plate and of a vertical plate are not entirely the same, and it looks as if the combination type must sacrifice something of the

Camp Bird Mill.

rapidity of the Ridgway and of the elasticity of the basket type for the sake of the greater capacity per unit. For automaticity can only be gained at the expense of elasticity, and hence it happens that the prettily running, apparently ideally simple Ridgway, with its perfect wash and its huge output per unit of filtering surface, needs for its effective working a strict adherence to the principle on which its design is based. The duty of a filtering machine is based on the amount of water or other fluid drawn through. The cake formation of residue is a sequel or a by-product, although for us it may be the all-important mat-

ter of tonnage treated per diem. Now, in a rapid-working machine like the Ridgway, it is evident that the amount of solution drawn through is mainly a function of time of immersion and not of amount of 'clog' or lessening permeability of cake. Assuming, then, that a standard Ridgway has a solution-drawing daily capacity of 50 tons plus wash, then when treating the 50% pulp for which the Ridg-

Slime Plant at Homestake Mill.

way was designed, it follows that 50 tons of solution drawn through leave as a deposit on the plates 50 tons of residue. If, however, a pulp of 66 or 75%

Experimental Plant at Taracol, Korea.

moisture is being handled, then 50 tons of solution drawn through leave behind only 27 or 17 tons, respectively, of slime-tailing as a daily output. It has become evident that for the successful working of automatic machines it is necessary to adhere rigidly to the condition of pulp thickness. With semi-automatic filters such as the Barry, Butters, Cassel, and Moore types this is not of so much moment. Here flow is a function of 'clog', as the cakes must be thick enough (four to eight times thicker than the Ridgway) to strip off a vertical frame. Possibly the last 1/8 in. of cake deposited takes 64 times as long to form as the first portion or section of similar

thickness, and thus if the solution is dilute one merely allows the cake a longer period of formation—it may vary from five minutes to one hour or even more—and adds a few more frames to make up for the greater time taken. The moral of this appears to be that if one wishes to use an automatic machine one must either have a 50% pulp or provide a suitable thickener, such as the Dorr, or settling-vats for this purpose. In Western Australia they find no difficulty in handling a pulp containing 55% solids; this is obtained by a constant flow from the first line of pointed boxes and an intermittent flow scraped down by a shovel from the second and third lines. In Africa in their settling-vats a pulp of similar thickness is encountered, but does not run with the same readiness. The more flocculent a pulp the greater percentage of moisture necessary to make it mobile. At Guanajuato we obtained a slime pulp by settlement so thick that it would stand up in ridges—like custard—after being stirred, and would not flow freely, and yet it contained 66% moisture.

Again, there is weathered slime so full of acid salts that gelatinous precipitate is formed on the addition of the alkali necessary to economical cyanide treatment. Success may scarcely be expected with this pulp from any of the automatic or semi-automatic methods employing filter-cloth, unless such salts are first removed by washing. Sand-filters such as the Hunt might be more successful, owing to the constant removal of the upper sand surface and the consequent automatic maintenance of an unlogged filtration surface.

Of the other methods, Moore's would probably have been more widely adopted but for the claim of patent rights over all submerged filters. When were filters not submerged? But more active business methods have during the middle portion of the year led to the securing of some contracts at Pachuca, Guanajuato, and Chihuahua. The process is necessarily more expensive to install than the Butters, but it has equal elasticity of treatment and the advantage of depositing on the dump nothing but washed tailing.

Barry avoids many difficulties by his special frame made of pressed corrugated sheet metal. There is no absorbent material inside the cloths, nor has he distance-pieces of wood on the face of his frames to offer resistance to the stripping of the cakes. His method is similar to the Moore, but differs in not necessitating a reversal of flow for discharge, and in permitting efficient agitation of pulp in the filter-vat. Then there are the pressure-filters of the Merrill and Burt types. I understand the former is still reeling off records merrily under its special conditions in South Dakota, but it is said to have been a failure in Mexico during the early part of this year—possibly the fault of local conditions. Burt is taking advantage at El Oro, as Merrill did in Dakota, of a gravity feed for his suspended-frame type of pressure-filter. It is difficult to understand how such a filter can wash its product prior to discharge. It was admitted to be discharging an unwashed output at both the mines at which it was installed in Mexico at the time of my visit.

Roasting. No improvements in roasting furnaces seem to have been made. The new Edwards furnaces have apparently given considerable trouble at the Lancefield, and they have been modifying the position of the auxiliary fire-boxes. The increased length seems to have tended toward the production of an unhandy unit.

Crushing. In Mexico the demand for an installation without stamps is continually heard. At one well known mine the Huntington mills installed were unjustly damned. Elsewhere poor success with Ferraris ball-mills is reported, and so the cry is for a simple installation using wet-crushing rolls. At Pachuca Capt. Narvaez is running Chilean mills, 8 ft. diam. by 16-in. face, with some success. These machines are of the slow-running type, making 10 rev. per min.; each wheel was stated to weigh 10 tons. For a consumption of 10 hp. each mill crushed 15 metric tons per diem from 1½-in. cube to a pulp 80% of which will pass through 200-mesh, at a cost, including 10% depreciation, of 70 centavos, or 17¼c. per ton; but I noted that this was on soft ore ('fines'); the hard rock was fed to ball-mills, and then to a tube-mill and crushed dry.

Reference has already been made to the installation of heavy stamps on the Rand. Mr. R. G. Fricker of the Gold Fields group, presiding at the recent Simmer & Jack meeting, showed that, largely as the result of using tube-mills, they have increased their profit on 7.6 dwt. ore from 12s. 9d. to 16s. 1d., or the addition of 3s. 4d. per ton, which shows a remarkable gain, attained entirely by increased extraction and lessened costs. He added that the introduction of tube-mills had had a marked effect on the mining conditions of the Rand, second only, perhaps, to the application of the cyanide treatment many years ago.

The following are some of the early tube-mill results: Redjang Lebong, without tube-mills, screen 35 mesh, output 2.85 tons per stamp per diem, extraction (sand) 79%; with tube-mills and 16-mesh screening, output was raised to 3.6 tons per stamp per diem, or 27% increase, for an 85.3% extraction. This ore is very hard.

Robinson Deep, with two tube-mills per 200 stamps, increased the output by 10%, and the profit by 1s. per ton milled. These examples of early results are given because they were obtained prior to the period of the use of lode-matter in place of pebbles for crushing and for liners. This later practice, modifying as it does both the power and the output, tends to complicate comparisons. Generally the tendency is to reduce the larger outputs per tube-mill obtained in 1906, and to use more power, so that already on the Rand the point has been passed where it is cheaper to increase output by tube-mills instead of by stamps. Ninety horse-power is now used for a 5 ft. 6 in. by 22 ft. tube-mill for an output of 140 tons per day, crushing through 60 mesh. But the increased extractions and the much lower residues, which have been reduced from 0.4 to 0.15 dwt., are tangible evidences of the claim for the present practice that the higher extractions obtained by the greater power employed are also the cause of higher actual profits. They do not appear on the Rand to have improved on the

costs of 5.71d. per ton of ore tube-milled, given in this review two years ago.

At El Oro, at first sight the impression is that the tube-mill is not being pushed to its full capacity, and that the horse-power consumed is high in proportion to the output of 1.1 to 1.2 tons per hp.-day. These figures do not shine in comparison with those of the Waihi, which also has a very hard ore, given in these notes for 1906, namely, an 18-ft. mill grinding 77 tons

The Ridway Filter in Plan.

of 20-mesh sand per diem so that 93% passes 150-mesh, with a consumption of $37\frac{1}{2}$ hp., but on closer comparison it appears that the classifying at El Oro was more thoroughly done than at Waihi, so that less actual slime is fed in the sand to the mills; that the standard of crushing at El Oro is somewhat finer; and that El Oro has done away with the use of pebbles and crushes with ore-lining entirely. Moreover, the El Oro policy of having a strong reserve of tube-mill capacity makes not only for comfort in management but in the ability to cope with the unexpected, and elasticity in treatment-method is probably responsible for the many accepted improvements in

Zinc-dust Precipitation Presses.

Showing part of cake in place at time of clean-up.

tube-mill practice which have come to us from El Oro. These are referred to later. They certainly have taken nothing for granted there, but have worked out their practice for themselves. At no other mill probably can be seen such a variety of tube-mills as at El Oro. In addition to two tube-mills of a make not preferred, they have five tube-mills of a well known make, three No. 3, one No. 4, and one

No. 5, the size preferred being the No. 3, 4-ft. diam. by 19 ft. long. The Waihi tube-mills are 5 ft. diam. by 18 ft. long, and, like those at the Knights Deep (Consolidated Gold Fields), are smaller than the usual Rand Mines standard of 5 ft. 6 in. diam. by 22 ft. long.

At El Oro for some time they used a special self-

Tube-mill in the New Plant of the Goldfield Consolidated.

filling cast-iron liner, previously mentioned in these notes, into which the flint pebbles jammed. This liner, however, is not so suitable for the use of vein-

The Ridway Vacuum-Filter.

matter, which has not the same jamming capacity as flint pebbles, and I therefore anticipate a modification of El Oro practice in this respect, as rough 'cubes' or otherwise irregularly shaped pieces of rock are not so amenable as pebbles for this purpose. About 53 lb. of rock in the form of 3-in. cubes is fed into the mill per ton of sand ground, and this abrades 0.2 lb. of cast-iron liner, the chips and frag-

ments of which are separated from the slimed sand by a 20-ft. blanket-strake. Silex linings were found to have a life of $2\frac{1}{2}$ months.

An ingenious device has been used at El Oro and Dos Estrellas, called the Neal discharge, which practically maintains an open end, through which the cubes, and at Dos Estrellas the rocks, are fed by belt, by chute, or by hand, as desired. The device is remarkably simple, and consists of an internal annular ring, or baffle, around the orifice, with or without a reverse-worm. This retains all pebbles, while permitting the egress of slimed pulp. I have referred before to the Barry lining, the cost of which at Waihi (fine sliming of hard ore) is 0.72 pence, or 1.4 cents, per ton of sand slimed. In Africa they appear to be still using local or imported silex at an apparent cost for coarse sliming of only three times this amount. In a recent paper Mr. Graham refers to "the set of 6 by 6 by 4-in. silex blocks put into our Davidsen mill with diamond cement, that has now run 165 days," which shows a vast improvement over former wear. They use a feed of 4-in. cubes, and Mr. Graham maintains that 8-in. lumps would reduce the effective life of the smaller lumps.

Not much has been heard of peripheral discharge, of late, but in Africa I was shown some remarkable results of tests made by the Crown Reef, using a Danish (peripheral discharge), German (ordinary trunnion discharge), and a local-type mill. At the first trial the local mill gave the lowest results, and was not further compared, but three tests were made of the peripheral mill against the ordinary trunnion-discharge, with the following results:

Trial No. 1.	Peripheral.	Trunnion.
Size of nozzle, inches.....	$1\frac{1}{4}$	$1\frac{1}{4}$
Rev. per min.....	26	28
Peripheral speed, ft. per min.....	408	425
Feed, tons per diem.....	251	260
Percentage of water	44	47
Discharge, decrease of + 60.....	43	31.5
Discharge, increase of - 90.....	42.2	25.4
Trial No. 2. (The nozzles of the two mills were changed.)		
Size of nozzle, inches	$1\frac{1}{4}$	$1\frac{1}{4}$
Rev. per min.	26	28
Peripheral speed, ft. per min.....	408	425
Feed, tons per diem.....	260	251
Percentage of water	47	44
Discharge, decrease of + 60.....	67.7	45.9
Discharge, increase of - 90.....	49.3	41.8
Trial No. 3.		
Size of nozzle, inches.....	$1\frac{1}{16}$	1
Rev. per min.	26	28
Peripheral speed, ft. per min.....	408	425
Feed, tons per diem.....	278	259
Percentage of water	35	35
Discharge, decrease of + 60.....	59.9	48.5
Discharge, increase of - 90.....	51.4	44.5

Thus is shown both a greater tonnage and finer grinding for the peripheral discharge.

I understand that a further test of a year's duration has been made at the Ferreira, and that, as a result, it has been placed beyond doubt that peripheral discharge gives better results than the ordinary straight-through trunnion-discharge. It will be noted that in the above tests no mention is made of flint charge or power taken. Peripheral discharge involves a loss of 4 to 5 ft. in height, and thus will

necessitate re-elevating for all mills laid down on straight-through lines which may be converted to peripheral discharge.

Concentration. The flotation methods appear to be causing a great amount of litigation. First we had *Potter v. Delprat*, and now we have the *Elmore v. The Mineral Separation Co.* The latter companies both claim success at Broken Hill on lead-zinc ores, but at Avino in Mexico, and at Cobar in Australia the Elmore process has not, under the local conditions prevalent, proved successful in practice. Of the mechanical concentrators, the Wilfley table still appears to hold the field, though I noticed a growing preference in Mexico for the Johnston vanner. Nothing appears to have yet been introduced capable of supplanting the plain table, whether of boards, canvas, or cement, for concentrating gold-bearing slime.

Slime Treatment. As under the heading of vacuum-filtration this subject has already been discussed, I may here summarize the present position by stating that in Africa decantation is still almost the universal method, but it is becoming evident that the days of this process, hugely expensive to install and incomplete in results, are drawing to a close. The recent admission that 7d. to 8d., or more, of dissolved gold per ton was being run away with the slime tailing, has promoted investigation into other methods of treatment. Dehne filter-presses, the Ridgway filter, and one or two other schemes have been put into practice or set to work on a practical scale, and in addition another method, known as the Adair-Usher, has been largely before the public eye. In America vacuum-filtration bids fair to completely throw out decantation and all other methods, though two advocates of pressure-filters are making a fight for it. In Australia filter-pressing still holds the field, but the Ridgway has some installations of considerable magnitude in operation, and the Cassel method has also been introduced at the Lake View. In India it has become obvious that the old method of taking advantage of the climate to deal with the sand and slime mixed must give place to some direct means of treatment, and the Ridgway has been installed on two fields for experimental investigation.

In eastern Asia a large Ridgway installation has been laid down where previously filter-pressing held the field, and another similar plant has also been acquired by another group, previously wedded to filter-pressing. It looks, therefore, as though decantation on the old lines, and even filter-pressing, is doomed to disappear, though in a less expensive guise decantation may still remain to form a portion of a more thorough process.

Adair-Usher. I looked into this process during my visit to Africa, in view of the great amount of publicity given to it by the technical press, and the great success and general adoption advertised. I have already referred to the lack of success attending upward percolation of solution and wash-water, as investigated by Holms in Mexico, Ward at Kalgoorlie, and Hunt in Costa Rica—did not Godbe patent this several years ago in the United States of America? At the first mine to which I was taken on the Rand I saw dirty solutions coming off from the vats

—surely evidence of poor work. At another mine, however, the Ferreira, I found a much better condition of affairs. There the metallurgist had apparently realized the impossibility of obtaining good extractions or of running off clean solutions by continuous upward percolation, and consequently he treated the process as merely an adjunct to the decantation process, to save a final transfer. He pumped his slime into collectors in the ordinary way, settled, decanted the water, and then transferred with dilute cyanide solution to the agitator-vats. After agitation for five hours the pulp was transferred to the Usher vat (an ordinary vat provided with a radial system of perforated pipes along the bottom), weak solution being fed through the perforated pipes during the charging, and indeed until the charge is 6 in. from the top of the vat or the decanter. The charge was then settled until the upper portion was quite clear, and then the solution was turned on through the radial perforated pipes at the rate of 10 to 12 tons per hour; this is for a 150-ton charge. This flow of solution was maintained for 36 hr. out of a total treatment time of 72 hr. The solution was then cut off and the charge allowed to settle, the solution being decanted to the agitator-vats. The Adair-Usher process thus becomes merely a method, not of solution, but of avoiding, with the aid of decantation, a final transfer. It has the advantage of saving the cost of one transfer ($2\frac{1}{2}$ d., or 5 cents), and of leaving the washing-vat free for other use. But as a matter of practical economics it is possible only in such a process as South African decantation with its huge plant, heavy pumping charges, and necessity for treble handling. It largely increases the bulk of solution to be handled—5 or 6 of solution to 1 of dry slime—and sends to the dam an amount of solution carrying not less than 4 to 6 grains of dissolved gold per ton, at least equal to the weight of the tailing discharged. From careful enquiries I could find no gain in extraction or decreased value of tailing resulting from the use of the Adair-Usher wash, but a saving of time and of vats from the avoiding of the final transfer and wash. In a word, as a solution-process the Adair-Usher seems to be no more feasible than the upward percolation tried elsewhere, and to have the same liability to mingle rather than to displace, and the same necessity for the employment of much solution, all taking up KCy and gold. Actual displacement indeed has not yet been recognized. On the contrary, alteration in 'head' or the slightest increase in heat of the solution pumped into the Adair radial pipes, causes an ascending stream through the pulp.

Clean-Up. I have referred elsewhere to the neatness of the Mexican clean-up plants based on absolutely the old safe lines of fine sieving and avoiding acid treatment and roasting. I am rather surprised that no one has tried T. K. Rose's method of purifying base bullion, and even precipitate, by introducing oxygen or air into the melt through a pipe-stem. Full details of this method were given in a paper presented to the Institution of Mining & Metallurgy, and from a demonstration in my presence it seemed that this process was most simple, even on base metal.

COPPER RIVER, ALASKA.

The U. S. Geological Survey issues the following interesting notes:

Active prospecting in the Copper River region was carried on in 1908 at the head of Nabesna river, on Cross creek (or Copper creek, as it is now called), and on White river. The White river prospects are situated in two areas—one at the head of the river, in the vicinity of Skolai glacier, the other near the international boundary line, partly, it is supposed, in Yukon Territory.

Prospecting in the region northeast of the Wrangell mountains is restricted almost wholly to the search for copper, although gold has been found at a number of places. The best known copper prospects on Nabesna river are near the foot of Nabesna glacier, in the vicinity of Orange hill, but development work is not yet sufficiently advanced to give an idea of their extent. At a gold deposit on Jacksina creek a small stamp-mill was erected in 1906 and about 60 tons of surface ore were crushed.

The copper minerals on Copper creek are found in lavas and consist chiefly of the sulphides, chalcopyrite and chalcocite, but include also cuprite and native copper. The copper deposits of White river consist of copper sulphides and native copper in lava flows. Native copper is found in greatest amount near the boundary line.

Prospecting in the Chitina valley was discouraged during 1908 by the low price of copper and the consequent difficulty of obtaining financial backing, but some effective development work was done. At the Bonanza mine the season was spent in erecting a sawmill, ore bunkers, buildings for various purposes, and an aerial tram from the mine to the camp. Development work was done on the extension of the Bonanza in the upper part of McCarthy creek by the owners of the Mother Lode claim and by the Houghton Alaska Exploration Co. The largest operations in the remainder of the field were those of the Alaska Consolidated Copper Co. on Nugget creek, the Hubbard Elliott Copper Mines Development Co. on Elliott creek, and the Great Northern Development and Alaska Kotsina Copper companies on the Kotsina river.

Probably the most important work affecting the future of the Copper River region is the construction of the railroad from Cordova to the interior. During 1908 more than 50 miles of track were laid, bringing the road to the bridge over Copper river between Childs glacier and the lake in front of Miles glacier. This road will establish steamboats on the river above Abercrombie rapids and it will be possible to carry freight from the coast at Cordova to Copper Center on Copper river or to the mouth of Lakina or Nizina river on the Chitina. Construction work is also being pushed on a short piece of road connecting the Bonanza mine with Chitina river, and its completion will make it possible to carry supplies to the mine or to ship ore to the coast before the whole of the railroad up the river is completed. A branch line to the Bering River coalfields is also under way.

SILVER PRICES IN 1909.

Written for the MINING AND SCIENTIFIC PRESS
By THEO. F. VAN WAGENEN.

The prospect for any large recovery in the price of silver in the near future is not bright, but there seems to be warrant for expecting a moderate advance within the next sixty or ninety days. In forming an opinion, or endeavoring to make a forecast, in this matter, perhaps the first step is to discharge from the mind the numerous stories afloat on the subject in the financial columns of the daily and weekly press. All such are doubtless set in motion through interested motives, and are not entitled to credence. Undoubtedly speculators are able occasionally to cause temporary abnormal fluctuations in the price of a commodity, but they must work with the actual ebb or flow of the tide to attain success. The next step is to examine the statistics of silver, its production and consumption, and apply to the problem the natural and well known laws of trade. The final element to be considered is the political one, for wars of any size, or conditions of unrest that generally precede them, by altering the rates of production or consumption, become factors in the determination of prices of staples.

The world's production of silver in 1907 was 6634.4 tons of 2000 avoirdupois pounds. This was an increase of 384 tons above the output of 1906. Seventy-eight per cent of the production originated in North and South America, 10% in Europe, 9% in Australia, and 3% in Asia (mainly Japan). From the best information at my command, not less than 85% of the whole amount arose as a by-product in the working of copper, lead, and gold ores. As the demand for these is strong, it may safely be inferred that there will be at least no material reduction in the quantity of silver produced during 1909. So much for the matter of supply. Now as to demand.

For scores of years past, Asia, mainly Hindustan and the Malay peninsula, has continuously absorbed fully 50% of the world's output. About 35% has of late years been bought by European and American governments for the production of new subsidiary coins, and the remainder has been consumed in the arts. There seems to be no probable call for any large amount of the metal from any other direction. India and Malaysia are as capable as ever of absorbing silver. The former, in fact, is advancing notably in commercial strength, and tin, which is the mainstay of farther India and the Straits Settlements, is firmly in demand. Throughout the civilized world (by which is meant Europe, North and South America, Egypt, South Africa, Japan, the Philippines, Australia, and New Zealand), the population is increasing, and new coinage is constantly needed. For a like reason the consumption in the arts is steadily growing. Hence, other things remaining the same, there is reason to believe that the demand during the coming year will be equal to the task of absorbing the supply, even if the latter should show an increase.

The problem then is reduced to the query: Will

other things be equal? Are the conditions during 1909 liable to be normal? Here enters the political element. What unusual thing may happen in international politics during the next twelve months? One important factor is certain. Wars not only cost vast sums of money, but they involve the destruction of an enormous amount of property, and in these days, when the financiers of the world are interested in commercial ventures almost everywhere, they become the real rulers; these are the men who decide whether wars shall or shall not take place. If England had needed to borrow money outside of her own people, she would not have been able to sell bonds to carry on the enterprise of South African conquest. If the Russo-Japanese conflict had been elsewhere than in distant Korea or Manchuria, where few foreign interests were affected, neither combatant could have raised the necessary money in Europe or America. There will be no wars in Europe. India, though full of unrest, will not be allowed to lapse into rebellion. Trade is King, wherever international trade exists. The business men of all the commercial nations insist upon its protection. Meantime the millions of Asiatics must live and consume, and to do so they must toil and export, and their exports must largely be paid for in silver. Normal political and social conditions may be anticipated during 1909, and the Orient will, as usual, absorb from 2500 to 3500 tons of the white metal.

The financial prophet has one more oracle to consult. That is the record of past fluctuations in the price of the commodity under consideration. Complete and accurate statistics as to silver for a number of years are available. These are embodied in the accompanying diagrams. Fig. 1 gives the average annual price of the metal since 1840. Fig. 2 gives the average monthly price during the last seven years. An inspection of the first seems to show that, after the tremendous depreciation caused by demonetization in 1873, production and consumption came again into approximate balance about the years 1894-97, since which time the fluctuations, though occasionally severe, have been due to normal variations in the general conditions of international trade. During the last 15 years the mean value of the metal, as shown by this table, has been 60.6 cents per fine ounce, with extremes of 52.16 and 66.8. The second shows a mean of 59.23c. per oz. for the last 7 years, with extremes of 47.5 and 71. The two exhibit close agreement, and it seems a proper conclusion that the normal value of silver, under international conditions as they have existed for the past 15 years, is about 60c. per ounce. As the year has closed with quotations ranging under 50c., an advance in the near future should occur. The advance during 1909 should be quite rapid, approaching 60c. before its close, with the promise of fairly steady prices during 1910-11, and a spurt toward top figures of 70 to perhaps 75c. in 1912. Beyond 75c. as an extreme, I see no chance for the white metal until the opening of China to the commerce of the world becomes effective, unless meanwhile, as would be

most wise, the chief commercial nations, acting together, should standardize their silver coinage, so as to prepare themselves for the coming day when the

The Occident has it, and to spare. It would look then as if it might be good policy for the latter to consider ways and means for strengthening the sell-

East will awake in earnest and begin to produce, and to force its products upon Western markets. The Orient wants silver, and will take nothing else.

ing price of a commodity that it would be glad to dispose of in large quantity, and for which it is likely soon to have a buyer.

MINING INDUSTRY OF THE MIDDLE WEST.

Written for the MINING AND SCIENTIFIC PRESS
By an OCCASIONAL CONTRIBUTOR.

A distinctly hopeful tone pervades the mineral industry of the Middle West at the close of what has been admittedly a bad year, although not so bad as was expected twelve months ago. In fact, a gain has been made in many lines; others have held their own; only a few have fallen behind. Business has been steadily improving. During the first week in December more cars and fewer empties were handled in and out of Indianapolis than for the corresponding week of either 1907 or 1906, and, as compared with any but 1907, the year 1908 has been regarded as extremely satisfactory. Pittsburg reports the pig iron production of the country for November to have been 1,580,444 tons, with 10 more furnaces in blast than in October, and 7 more about to start.

In Illinois, for the year ending June 30, 1908, the coal production was 49,272,452 tons, as compared with 47,798,621 tons for the year ending June 30, 1907. For the calendar year, the output has been maintained, if indeed a slight gain was not made. This, in the face of the prevailing business depression, is worthy of remark. It is doubtless due to the enormous expansion that our coal industry is undergoing, amounting during single years to a growth of over 25%. This year the natural growth, largely in sales of domestic coal and fuel for heating, lighting, and traction plants, offset the decrease in demand for railway and manufacturing purposes. In Iowa, where factories take a still smaller portion of the output, the depression was felt even less.

The year has seen the opening of more coal mines in southern Illinois despite the present excess of capacity over market. The new plants are excellently designed, steel top-works now being the rule, and the permanent plants being of much higher grade than those installed a few years ago. This is necessary owing to the larger outputs handled—2000 to 3000 tons in 10 hours—and the greater depth of the mines. Unfortunately less attention has been paid to adapting underground systems to the new conditions. There is entirely too much of a disposition to use the same methods and men as in the shallow outcrop mines, despite the greater risk of fire and explosion. As a result, an increasing number of serious accidents has occurred. In November, within one week, in a single district not more than a dozen miles across, the Rend mine exploded and killed four men, the accident being followed by an underground fire; the Zeigler mine had a serious fire which, because of the absence of a panel system, spread so rapidly as to require sealing of the mine; and finally, the Benton mine blew up. Now, within a month, a second explosion has occurred in the Rend mine, due, it is stated, to escape of gas from the sealed off burning part of the mine. Evidently better skill is needed in this field, and not unlikely the Legislature will be asked to modify the mining law to meet the new conditions.

In the meantime arrangements have been made

for the U. S. Geological Survey to establish at the University of Illinois a branch rescue station for training men and furnishing apparatus for service at explosions and mine fires. Messrs. Paul and Rice, of the Pittsburg station, assisted at Zeigler and Rend, using the Draeger oxygen helmets. Their services were so valuable that a demand has been made for a branch station to serve the Illinois, Indiana, Michigan, and western Kentucky coalfields. It is understood that the University will furnish the building, including a gas chamber for practice training, and the U. S. Geological Survey will furnish the portable apparatus and detail a mining engineer to take charge. The Operators' Associations will furnish two men per week from the various mines to receive the training and to assist in case of an emergency call. It is expected also that all Mine Inspectors will become familiar with the work, and that ultimately all the larger collieries will be equipped with rescue apparatus.

G. W. Traer, president of the Illinois Coal Operators' Association, has resigned his position as receiver of the Illinois Collieries Co. This ill-fated concern will be remembered as one of the creations of Robbins, of Pittsburg, who, during a boom period, bought out the Jones and Adams and a string of other nearly exhausted collieries in central Illinois. To these were added large coal-land holdings belonging to Minneapolis people. The attempt was made to pay interest on bonds representing the whole property and to get into the Northwestern market. The attempt was a failure, in part because of the natural competition in this market of the higher-grade coal of Mr. Robbins' other mines in the Pittsburg district. The management was changed, and Mr. Traer took hold, first as president, and later as receiver. He has made a good fight to maintain the property, but in the absence of railway affiliations a coal mine in the Middle West has a hard time. Mr. Traer brought suit before the Interstate Commerce Commission and obtained a ruling compelling a much fairer car distribution than has prevailed. His presentation of the case was so complete and accurate that the railways made no defense and the Commission entered the ruling asked for. None the less, the time is too early for a large independent coal company to be successful in reaching the Northwest market, and it is understood that in future the Illinois Collieries Co. will be operated mainly for the local market.

Among miners, interest centres now upon the election of an international president of the United Mine Workers, in the place of John Mitchell. Tom Lewis, who followed him, seems not to have been successful. There has been open rebellion in Indiana and Pennsylvania, and serious trouble in Arkansas and in other States. It is said he has systematically tried to eject Mr. Mitchell's friends, and to create a personal machine within the organization. However that may be, he is regarded by operators as being demagogic and inclined to promise for effect more than he can accomplish. Since the United Mine Workers, including 350,000 of the 600,000 coal miners of the country, is the largest single interest in

the industry next to the anthracite coal operators, the election of an executive chief is a matter of wide moment. Mr. Lewis' opponent is John Walker, of Illinois, who is regarded as the true heir to the Mitchell policies and following. While Mr. Walker is an avowed socialist he is, singularly enough, the wiser and more conservative leader of the two. As one operator phrases it: "John doesn't let his socialism interfere with his common sense." He is everywhere recognized as honest and fearless. Present indications point to his election.

It is probably fortunate that no unusual demand for coal occurred this fall in view of the shortage of water. The washeries were mostly compelled to close and many mines could keep up steam only by hauling water. All tank-cars were put in service, and gondolas lined with rubber blankets were used. Freight and even passenger service was crippled, and locomotives limped along from tank to tank, taking a small drink here, a smaller one there, and a good one nowhere. Any kind of water was at par, resulting in numerous breakdowns, and in joy only for the makers of boiler compounds. In some towns the water was held by the Board of Health and given out under police regulations. The drought has been broken, but there is still a shortage in places; this raises serious questions as to what will be done when, as statisticians tell us will happen inside of a century, we have four times as many people to supply.

In one direction the water shortage was something of a blessing in disguise: it practically stopped drilling over much of the oilfield. Since tanks are full, and pipe-lines are taking over 60% of the oil offered, it manifestly is folly, collectively, to bring in new wells, regardless of the individual advantage. Only the widespread and rather unusual spirit of co-operation that has obtained in the Illinois oilfield, and the skill and energy of the local Standard Oil officials, have permitted the situation to be handled without a break in price. As it is, there have been only 15 days (early in June, 1908) since the field was opened when all oil offered was taken. This brought it out at the rate of about 3,000,000 bbl. per day, and the output for the year, despite all efforts to decrease production, will run 35,000,000 bbl., or better. The oilfields continue to expand. Within the year production has begun, at least in a small way, at Sparta, in the western part of the State. At Centralia an 18-bbl. well is being pumped in a wholly new district, and favorable showings are being obtained in other 'wild-cat' areas. It is reported that the Indian Refining Co., which has previously shipped to its plant at Georgetown, Kentucky, will build a large refinery at Lawrenceville, Illinois, near its wells. The Pure Oil Co. is completing an independent pipe-line eastwardly. On the whole, the Illinois oil industry is in a prosperous condition.

The lead and zinc smelters of the Mississippi valley have suffered throughout the year. The mines have kept up production fairly well, but it is doubtful whether they have made much money. The most significant change in the Wisconsin district has been the entrance of the U. S. Mining, Smelting &

Refining Co. Interests affiliated with this company have bought the famous Empire and other good producers and have erected a large mill for treating the ore by a new magnetic process. It is noted, however, that they are also building mills of the old type with roasters. The Empire, by the way, on an initial investment of \$30,000, distributed approximately \$250,000 in dividends, and is said to have gone into the new combination on the basis of \$100,000 in cash and 15% of the stock of the new concern.

The cement industry, closely dependent as it is on building operations, has languished throughout the year. The Sandusky Portland has taken up the contest with the North American over the Hurry and Seamon patents. This will be watched with interest, since the only possibility of monopolizing the cement industry seems to lie in the ownership of basic patents. It will be remembered that the Pennsylvania case was settled out of court on the basis of payment of royalties by the contestants.

Record progress in driving hard-rock tunnels was discussed in our issue of June 6, and it was there stated that the American record for machine-drilling was made in the Gunnison tunnel. That record of 449 ft., made in January, 1908, has now been exceeded in the Elizabeth Lake tunnel, a part of the Los Angeles aqueduct. For the 31 days ending at midnight, October 31, the south heading was driven a total of 466 ft. The Elizabeth tunnel is the opening by which the waters of the Los Angeles aqueduct will be carried through the crest of the Coast Range. The tunnel is to be 27,215 ft. long, of which 355 ft. is in open-cut, giving 26,860 ft. from portal to portal. It is about 60 miles north of Los Angeles, and the south portal is 24 miles from a railroad. The Elizabeth tunnel is 12 by 12 ft. in section and is driven in granite rock. It is interesting to note that the Elizabeth tunnel and the Gunnison tunnel were driven by day labor, under the direct charge of engineers of the Government and of the municipality. The Elizabeth tunnel was driven full size by the lower heading method with Model 6-A water Leyner rock-drills. The mucking was done by hand and the dirt transported by electric motors. The face, October 31, was 2508 ft. from the portal. The base rate in the bonus system employed is 8 ft. per day, or 248 ft. for a 31-day month. For each foot in excess of this amount each man working in the tunnel continuously during the month is paid 40c. Including the payment of the bonus, the month's run was made at a cost of \$35.81 per foot, and at the rate of 15 ft. per day. The run of 466 ft. was made with modern tunnel equipment, consisting of two 520 cu. ft. Franklin two-stage air-compressors, each belt driven by a 100-hp., 440-volt A. C. induction motor which supplies air for the rock-drills and other equipment; one Fairbanks-Morse 100-kw. motor-generator set, supplying direct current at 220 volts for operation of one six-ton electric locomotive, used in tunnel traction, and one No. 7 Root blower. This equipment is duplicated at the north portal. The work is in charge of J. B. Lippincott, assistant engineer to the Water Works, and W. C. Aston, tunnel superintendent.

COPPER MINING AT ELY, NEVADA.

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DE KALB.

The name of Ely was not transferred from Vermont to Nevada. The classic little copper mine in the Green mountains, never large, but never exhausted, had nothing to do with naming the spot in the Steptoe valley that has risen suddenly to fame. Many years ago, the abundant water and excellent pasturage in this valley led to the establishment of a cattle ranch by one Ely from "down in Maine," and Ely's Ranch became simple Ely. In course of time, minerals were discovered. First came lead ore, containing silver. Lead is still mined in the district and is shipped to Salt Lake City. Next gold attracted notice. The Chainman mine once gave promise of acquiring a reputation, but the mill, dragged 140 miles from the railroad, has succumbed to rust instead of wear. This is at Lane City, on the road up the gorge to Copper Flat, the scene today of magnificent operations in the gigantic modern way. Close to this great open-cut is the Keystone copper mine, memorable only for a tragedy in which a mine manager shot four menacing workmen several years ago. This mine, like others around it, was a failure. A large dump betokens extensive workings underground; to the Nevada Consolidated Copper Co. this dump of gray slacking monzonite is commercial ore, and will one day go to the mill, when the excavations extend that far; to the Keystone capitalists it was 'waste,' and typified discouragement. It depends on the point of view what kind of an enterprise is set in motion. The disseminated ores of Ely to the first group of miners signified the possibility of enriched veins, from which they hoped a product might be obtained that would pay the enormous costs of old-time methods. The second group, urged by the courage and inspired by the foresight of Mark L. Requa, instead of seeking ore to match a method, adapted a method to the ore available, and the result is one of the greatest copper enterprises in the world. The shares of the Nevada Consolidated, which could be bought during the late panic at \$6, are now close to \$20. The capital stock consists of 1,600,000 shares, of a par value of \$5 each. So clearly was the future greatness of the property proved that the capital stock and other securities realized a sum of \$3,122,710 in excess of par value for the benefit of the company's treasury. The total capital liability on the books today is charged at approximately \$14,400,000. This finds its warrant in a body of developed workable ore of 20,000,000 tons. The reserves blocked at present represent only a fraction of the area available. Prospecting by Keystone drills is proceeding rapidly; this is a swift and exceedingly economical method of prospecting. The ordinary drill, such as is used in testing auriferous gravel, is employed: the prospect holes extend to 300 and 400 ft., according to the topography, but the hole is usually started with a diameter of 10 inches, so as to finish at 6 in. The speed varies from 25 to 40 ft. per diem, and the cost ranges from 75c. to \$1.25 per foot. This work is locally called 'scouting'. The testing already

done shows an average copper content for the 20 million tons developed, of 1.9%, this being the figure stated officially by Pope Yeatman, the consulting engineer for the company.

The earlier testing of these deposits was done by the ordinary methods of shaft-sinking and level-driving. This was mainly at the Ruth mine, on the eastern side of the mass of impregnated monzonite. An account of the tests, and the vindication of the churn-drill method by its faithful agreement with sampling in many lots of several hundred tons in the Ruth mine, will be found in an article entitled 'Experimental Mill of the Nevada Consolidated Copper Company', by M. L. Requa, published in the MINING AND SCIENTIFIC PRESS of July 18, 1908.

The area of the ground owned by the Nevada Consolidated Copper Co. is 850 acres, consisting of 63 claims. Closely related for purposes of operation and treatment is the Cumberland-Ely, where 12 claims have been partly developed. The orebody there is narrow, and of higher grade, yielding from 3 to 4% copper. Associated with these companies are the Steptoe Valley Smelting & Mining Co., with magnificent works, still being enlarged, at the new town of Smelter, 22 miles away. Here water is abundant, and ample precautions have been taken not to become involved in legal embarrassments over fume. Finally, the Nevada Northern Ry. Co. was organized, and a line was built to the Southern Pacific at Cobre, 140 miles north of Ely. A ramification of shorter lines around Ely opens up the ore-producing territory and gives access to the works at Smelter. Each corporation is operated on entirely independent lines. Beyond these corporations lie other financial intricacies, the American Smelters Securities Co. holding indirectly a controlling interest on behalf of the American Smelting & Refining Co. Thus the enterprise constitutes a notable enrichment of the holdings of the Guggenheims.

The geology of the ore deposit was studied by Andrew C. Lawson, professor of geology in the University of California; a monograph entitled 'The Copper Deposits of the Robinson Mining District, Nevada', was published in 1906, as a bulletin of the Department of Geology in the State University. No preceding studies had interpreted the interesting phenomena presented at Ely. Under conditions that were practically those of a reconnaissance Mr. Lawson has done work that has stood the test of subsequent development, so that his report on this property has been a splendid example of the practical importance of the economic geologist. In brief, a mass, or batholith, of monzonite porphyry is found intruding Devonian and Carboniferous rocks, the latter consisting of limestone. The intrusive rock appears upon the surface at Copper Flat and at the Ruth mine. The area between is overlaid with limestone, and this covering exists continuously around the porphyry, portions of which are also overlaid by a more recent flow of rhyolite. This has raised the question as to the probable extension of the copper in workable amount beyond the limits of the exposed area, especially under the rhyolite capping. A concentration by secondary enrichment has resulted

from leaching where the monzonite has lain open to meteorological influences. The enrichment has been feeble, to be sure; nevertheless it has made all the difference between ore and valueless rock. The upper portion of the porphyry has been impoverished by leaching, and constitutes an overburden from 50 to 70 ft. thick, containing 0.75% or less of copper. The re-precipitation occurred at a former water-horizon which has since been lowered. Hence the change from the overlying oxidized lean rock, with its prevailing yellowish tinge, to the bluish-gray enriched ore below, is as abrupt as if the two had been artificially severed. Below this line of division, however, the copper content presently shows a decrease in depth, and the quantity gradually sinks to about 1 per cent. The depth to which extraction may continue depends, in consequence, upon the price of cop-

was early foreseen, and it has fulfilled the expectations of those who fathered the enterprise. The cost of the ore in the cars ready for transportation to Smelter is about 40c. per ton, including its proportion of the cost of stripping overburden. The actual digging and loading costs only about 11c. per ton. One 70-ton and three 95-ton Bucyrus steam-shovels are used. The larger shovels, with $3\frac{1}{2}$ cu. yd. dipper, equal to 7 tons of ore per dipper, will dig as much as 800 cu. yd. per day. A shovel-crew comprises an engineer at \$175 per month, a crane-man at \$125, a fireman at \$90, and 6 pitmen at \$2 per day. The cost of explosive used on the overburden will not exceed 4c. per cubic yard. A shovel will comfortably load 2500 tons in 9 hours, and it can fill one car of 55 tons in 4 minutes. The banks worked in the overburden are at present about 50 ft. high, and

Mining With Steam-Shovel at Ely.

per and the extent to which mining and reduction of the ore at Ely can be cheapened. An interesting phenomenon at Copper Flat is the vertical division of the deposit by an almost dike-like zone of silicious ore, out-cropping on the surface and cutting the deeper orebody. This contains copper to the extent of 3%, and even 4%, in the form of silicate and carbonate. It was originally suggested that this so-called 'carbonate' ore would need to be treated by a leaching process, but the metallurgists of the Steptoe Valley S. & M. Co. have done better than that. The proportion of silica is so high, being about 80%, that in this material, donated by Nature as a bonus with the mine, they have an ideal converter lining. This enricherous silica, available at certainly no more than 65c. per ton laid down in the works, is an important assistant in the economical treatment of these ores.

The method of mining adopted at Copper Flat is by steam-shovel. The adaptability of the steam-shovel

in the ore 40 ft. The open-cut is 800 ft. long by 400 ft. wide, and is being excavated in two benches, with railroad track making a loop around the head of the cut, so that trains always make the circuit, thus obviating loss of time from switching in and out of the loading places. Much of the ore is soft and requires little or no blasting, but the overburden is hard and needs shattering by heavy blasts. Holes for this purpose are drilled with Keystone churn-drills, using a 6-in. bit. No casing is required. The holes are placed from 25 to 30 ft. from the edge of the bank, and 30 ft. apart. The hole is first 'sprung', or chambered, with dynamite, from $\frac{1}{2}$ to 2 boxes of 40% grade being used, according to the hardness of the rock. If the ground is relatively loose the hole is then charged with 60 kegs of 25 lb. each of Dupont FF black powder, if the rock is firm and dense, the hole is loaded with 15 to 20 boxes of 40% dynamite. The volume moved by such a blast is approxi-

mately 2400 cu. yd. Work had been abandoned during the financial crisis, but stripping overburden was resumed in March. Since that time, approximately 300,000 tons of sulphide ore have been mined and shipped to Smelter. This applies only to Copper Flat, and is exclusive of tonnage shipped from the Veteran mine of the Cumberland-Ely. Drilling is proceeding westward to establish the persistence of the orebody in that direction. In horizontal distance these tests have shown its continuance 1800 ft. beyond the present open-cut, and the cut will have several banks or terraces below the existing floor. This will give an idea of the magnitude of the operations. It was hinted that banks 100 ft. high might be attempted, which would, of course, be in disregard of occasional mishaps, when a shovel and crew might be buried by a slide. No extraction of ore is taking place at the Ruth mine. The amount cheaply available at Copper Flat is enough to feed the mill, as it now stands, to its full capacity, and concentration of work and traffic at one point naturally affords superior advantages in regard to economy.

The Veteran mine, which is practically part of the same general scheme of operations in spite of pertaining to a company having a separate corporate existence, is an underground working. The overburden here is too thick to admit of stripping. That form of caving known as 'top-slicing' is being introduced. Enough has been done to demonstrate its applicability to local conditions. The ground is laid out by cross-cuts and lateral drifts in blocks 50 ft. square. Raises are then driven to the overburden at the four corners of the blocks. The slicing is carried across each 50-ft. block, and a floor of boards laid as the work progresses, to serve as a mat to hold the overburden when it settles, and to keep it from mixing with the ore below. The height of face on the upper slice is 8 ft., but the subsequent lower slices will be 10 ft. The next slice will be worked carefully under the broken overburden, the mat being caught and held in place by timber sets of 12 in. square caps, and round stulls of Oregon fir. As the system had only been introduced experimentally, no data concerning costs were available. Fifty experienced cave-miners had just been brought from Minnesota. The output of the Veteran is intended to be 1500 tons daily. Four of the 12 claims on the orebody will be worked from this one shaft. The charge made by the railroad on ore from the Veteran mine to Smelter is 30c. per ton in 300-ton lots.

A vertical 3-compartment main shaft, with manway, serves the Veteran mine. The compartments are $5\frac{1}{2}$ by 6 ft., with one compartment $5\frac{1}{2}$ by 9 ft. for convenience in lowering timbers. The shaft is surmounted by a wooden head-frame 110 ft. high, with 12-ft. sheaves over which run $1\frac{1}{4}$ -in. steel cables. The total height of lift is 600 ft. Hoisting is done in automatic-dumping 5-ton skips made by the Atlas Car & Manufacturing Co. of Cleveland, Ohio. A cage is also used for raising and lowering men; this is operated by a special steam hoisting-engine, designed and built by the Exeter Machine Works of Pittsburg. The ore-skips are operated by a 300-hp. General Electric Co.'s induction motor,

rated as 3-phase, type 1-14, form M, 60 cycle, for 290 amperes and 550 volts. The hoist itself was built by the Denver Engineering Works and has 6-ft. drums, working in counterbalance. A current of 40,000 volts is transmitted from the power-house at Smelter, and is stepped down to 600 volts for the hoist.

The geology of the region is of great interest, but the details are accessible in Mr. Lawson's published report, and will not be reviewed here. Attention, however, may be called to the fact that indications are favorable for the existence of contact copper deposits between the porphyry and the limestone; these possibilities have not been developed. It is expected, however, that ore available for blast-furnace smelting will be found. The limestone contains many large masses of silver-bearing limonite, which would furnish valuable flux for silicious copper ore. That the silver-lead and gold ores will be locally utilized in time seems probable. Developments are disclosing larger amounts of galena than had been previously suspected. These deposits constitute a distinct belt north of the monzonite, and lie in the Ruth limestone, which is the upper member of the Carboniferous rocks occurring in this district. The Ruth limestone is 500 ft. thick, and is underlaid by 1000 ft. of Arcturus shaly limestone, succeeded downward by 1500 ft. of Ely limestone. Thus there may be possibilities for lead-mining at considerable depths below the present known occurrences in the Ruth limestone. Some deposits of lead-ore are also being worked in a small way on the great ridge that separates Steptoe from Duck Creek valley. These small mines, which are now shipping ore to Salt Lake City, are almost directly above the reduction works at Smelter. The gold deposits are confined to the Paleozoic rocks, which are represented by 1000 ft. of White Pine shale, on which the Ely limestone rests conformably. Below this comes the Nevada limestone, at least 1000 ft. thick. These are of Devonian age. The gold ores are often basic, and to some extent may be used as flux if blast-furnace smelting should develop at this point, and it has been hinted that some concentrating gold ore exists.

Surrounding the great mines are others of varying promise. The Giroux Consolidated is well known, having been long before the public. Underground mining is practiced here, and it would seem that the policy of the company has been too much to insist upon the importance of its rich ore rather than to face the larger elements of the problem presented in the utilization of masses of low-grade ore by the cyclopean methods that are now changing the character of copper mining in so many parts of the world. The Giroux undoubtedly has rich ore, but it seems unfortunate that no energetic effort is being made to open what may prove so large a mine that the high-grade masses will only be looked upon as something to sweeten the output. Many prospects are being worked, as always happens around every enterprise of magnitude. Despite their reputation, the Guggenheims have not taken everything in sight at Ely. Combinations of outlying properties may lead to the creation of important neighbors for the Nevada Consolidated and the Cumberland-Ely.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Forest Reserve and Mining.

The Editor:

Sir—The administration of the Forest Service, in so far as it relates to the miner and home-seeker, has been the subject of much adverse criticism: Mr. Gifford Pinchot, in his reply to an editorial in the *Denver Evening Post*, says: "The Forest Service has always invited candid criticism and co-operation of the people of the West in its attempt to give them a steadily more helpful administration of the National Forests, but it insists that criticism, to be helpful, must have some relation to the facts." Having made an examination of many of the claims in Plumas county, California, that have been contested by the Forest Service, I feel qualified to meet the conditions that the Forest Service imposes upon those who offer criticism.

Mr. Pinchot states in his reply that "the Forest Service has never denied a patent to any mineral claim in any National Forest, nor declared the same invalid, for it has no right to do so. But it is the duty of the Forest Service under the law to report to the Department of the Interior, upon its request, the actual facts on the ground concerning any claim or location within a National Forest, to enable the Department of the Interior to form a judgment as to the validity of such claim or location. The Department of the Interior forms that judgment and acts upon it—the Forest Service merely reports such facts as it finds. It is not the judge, but merely a witness in the case." This is merely an attempt to shift the responsibility. The Forest Service has been most active in its efforts to exclude the miner and home-seeker from the Reserve. The Forest Service seems to consider that its principal duty is to depopulate the country in favor of timber-culture.

Before the creation of the National Forests the prospector in California was free to locate and record mining claims; to prospect and develop them in his own way, and at a time best suited to his interests; and he remained in possession as long as the requisite amount of assessment work was performed each year. This was the law. Many a farmer has occupied his idle winter months in 'drifting' for a back channel that might require years of his work to reach, his only justification for the work being his faith in the existence of such a channel.

The Use Book of the Forest Service expressly states that the miner and home-seeker shall be accorded the privileges they formerly enjoyed before the creation of the National Forests. But there is an unwritten law: that the prospector must be able to prove the mineral character of the ground he has located at any time the Forest supervisor or his rangers see fit to question the validity of his location. It is not sufficient that the ground shows encourag-

ing prospects, or that there is every indication of an ancient channel; it must be shown to be profitable mining ground, "more valuable for the mineral than the timber." This virtually means a cessation of all prospecting within the Forest Reserve. No miner cares to risk either time or money in prospecting a claim when the right to continue the work may be denied him at any moment.

The methods employed by these Government experts in determining the character of the land are interesting: In one instance a pit was dug to the depth of five feet; a surface inspection sufficed in all other cases. It is true that where bedrock is exposed on steep hillsides and ridges, the character of the land may be determined by a superficial examination, but can it be foretold what lies beneath the surface of the soil, gravel-bank, or lava-cap, without recourse to shafts, drifts, or bore-holes? Yet the prospecting work of these experts who declared the contested Yard claims to be non-mineral, was limited to a few pans taken from the surface.

While the miner is merely denied the right to prospect and hold claims within the Forest Reserve upon the testimony of the Government officers, the home-seeker is subject to arrest and imprisonment. I refer particularly to the contested case of William H. Beatty. The property known as the Beatty homestead, situated in Butterfly valley, six miles from Quincy, Plumas county, California, was filed upon as a homestead by John Brinker in 1887. The improvements were bought by William Maxwell in 1892, who afterward sold them to Beatty, and thereafter the place was continuously occupied by him and his family until after application was made for patent, which application was granted in March, 1905. Beatty remained in undisturbed possession of the property, and it was finally sold by him, no patent yet received.

Last winter Beatty was placed under arrest by a United States marshal and, refusing to give bail, he was transported to Alameda county and placed in the Oakland jail, and there confined for a considerable time, until bail was furnished by residents of Quincy. His arrest and subsequent indictment on the charge of perjury in having sworn falsely to a homestead affidavit was brought about by the testimony of Edward Doyle, Frank H. Smith, G. A. Hall, and LeRoy A. Moore. The charging part of the indictment reads as follows: "As he, the said William T. Beatty, thus and there well knew, the said land was then and there mineral in character, and as he, the said William T. Beatty, then and there well knew had been successfully mined for gold, and that large quantities of gold had been taken out of said land; and whereas, in truth and in fact the said William T. Beatty then and there well knew that a large portion of the said land had been heretofore and was then and there worked for mineral and that the said land was then and there essentially mineral instead of non-mineral, whereby he, the said William T. Beatty, did then and there commit wilful perjury."

From a personal examination of the property, I can state that the contested portion of the homestead is not profitable mining ground; that the land was

thoroughly prospected and abandoned years ago, until Frank Smith, now a Forest ranger, and his brothers resumed operations some three years ago, long after Beatty had made his homestead entry; that the amount of material washed by them did not exceed 2700 cu. yd., and that it could not have yielded over 40 cents to the man per day; that they have for some time suspended operations, and removed their sluice-boxes from the property.

The remaining ground within the confines of the property available for mining purposes is less than one acre. Any person would have been justified in considering the land more valuable as a homestead than for its mineral content.

Beatty is highly respected; he has the sympathy of the entire community against the Forest Service in his struggle for justice.

There is a general feeling of dissatisfaction among the residents of Plumas county in the present administration of the Forest Service.

Flotation-Process Litigation.

The Editor:

Sir—As your London correspondent I have, from time to time, referred to litigation in the English courts between the owners of the Elmore and Ballot-Sulman-Picard patents, for concentrating ores by means of oil. The decision given in the Court of Appeals on December 2 bids fair to end this long dispute, and to place the control of the oil-flotation process in the hands of the Elmores. The judgment reversed the decision of the Court below given by Mr. Justice Neville five months ago. The Court of Appeal consists of three judges, one of whom in this case was Lord Justice Fletcher Moulton. This judge is prominent as a lawyer with a special training in science. He was senior wrangler at Cambridge, and has always been noted for his grasp of technical details. He prepared the judgment of the Court, in which his colleagues joined unanimously. The decision was not rendered hastily; two weeks were taken for preparation and consideration. The defendants may appeal to the House of Lords for final argument, though that court is not likely to differ in opinion from an eminent judge thoroughly familiar with his subject. An interesting point in connection with this trial is that Fletcher Moulton, before becoming judge, advised in his capacity as attorney on the original Elmore specification. When he found this case on his list of trials he notified both parties that this fact would prevent him from sitting in judgment. Both parties, however, assured him of their confidence in his fairness and freedom from bias; in fact, they both specially desired the case to go before him on account of his familiarity with the subject in hand. The point was a small one, for he had given his professional opinion on the original Elmore specification before the existence of that taken out by Ballot, Sulman, and Picard.

The question in dispute was whether the Minerals Separation Limited, operating the Ballot-Sulman-Picard patent, were infringing the Elmore patents of

1898 and 1901. These describe the old oil-flotation process, which has since given way to the improved form known as the vacuum process. The 1898 patent claimed "separating the metallic from the rocky constituents of ore by mixing the pulverized ore first with water in considerable quantity, then adding to the mixture an oil, consisting of a thick tarry residue of mineral oil after some of the volatile constituents have been driven off, the said oil adhering to the metallic constituents but not to the rocky constituents, allowing the water carrying the rocky material to subside while the oil carrying the metallic constituents floats above." The specification of the 1901 patent claims the "addition of a small proportion of acid to the mixture of ore, water, and oil, such slight acidulation greatly enhancing the selective action of the oil." In the Ballot-Sulman-Picard patent of 1905 reference is made to small quantities of light oil and acid, which are energetically beaten into contact with the mixture of ore and water so as to produce an aëration of the mixture. The patentees argued that of the three known physical reasons why oiled metallic particles are enabled to float, they depended solely on surface tension and aëration, while the Elmore patents of 1898 and 1901 relied solely on the third, namely, the specific gravity of the mixture of ore and attached oil. Lord Justice Fletcher Moulton quoted on this point the maxim that an inventor did not have to explain the scientific principle on which his process acts, and he also urged that at best our knowledge of the rationale of the flotation processes is incomplete, so that he was unable to base a judgment on this conception of principles utilized in the various inventions. He found that the 1898 invention was the valid one, but that, as the patentee expressly mentions a thick oil, the defendants' patent of 1905 did not infringe it, seeing that they specially claim a thin oil. On the other hand, he held that the use of small quantities of acid in assisting the selective action of the oil was undoubtedly first disclosed in the Elmore 1901 patent, and therefore the Ballot-Sulman-Picard patent of 1905 infringed it as far as the use of acid in conjunction with oil is concerned. The result of this judgment is that the Elmores may claim priority in all processes where oil and acid are used. After this decision it would seem to be reasonable to effect a consolidation of interests at stake. The Elmores are blocked by Ballot, Sulman, and Picard in the use of thin oils; on the other hand the Ballot-Sulman-Picard patent is practically stripped of its value by the ruling as to the use of acid. The concentration processes using oil and acid are thus brought under the master patent of 1901. From a broadly economic standpoint it is well that the oil-flotation process is now freed from the embargo of legal disputes. Metallurgists may now develop the practical possibilities of the method without fear of disastrous lawsuits. It is noteworthy that no mention is made of the buoying action of gas-bubbles generated by the acid, but this was not the matter in dispute, although it is a phenomenon that plays an important part in all modern flotation processes.

EDITORIAL.

IT IS a pleasure to record that Mr. Lewis H. Beason, who has long served the MINING AND SCIENTIFIC PRESS as special correspondent at Salt Lake City, has become editor of the *Pioche Record*, at Pioche, Nevada. We tender Mr. Beason our best wishes for success in his new venture.

MINING MEN interested in northern Mexico will be glad that the Yaqui troubles in Sonora seem to be at an end. About 5000 of these Indians surrendered at Nogales on January 4 and signed a treaty of peace. Some of the tribe remain in the hills, but their chief Bulle has promised to aid the Mexican government in pacifying them.

IRON statistics are said to furnish a barometer of trade. This is measurably true. Orders are placed so far ahead, however, as to modify the sensitiveness of this commercial indicator. The extent of the depression in 1908 is shown by the fact that the output of iron from the furnaces of the United States was only 15,486,606 tons, as compared to 25,292,335 tons in 1907 and 24,749,984 tons in 1906.

GOLD production in the Philippines made an extraordinary advance in 1908. From 64,700 fine ounces the year before there was a sudden leap to 306,708. These are official statistics, representing receipts at the Mints of the United States and purchases by the American Smelting & Refining Company. Considerable quantities of Philippine gold are marketed in other countries, but no estimate of such contributions to the output is attempted in the figures given. The possibilities for mining in our eastern dependency are attracting the attention of capitalists.

THIS is the season when the statistician takes himself seriously and the public absorbs columns of crude arithmetic in the fond belief that they express irrefragable facts. Of course, there are statisticians and statisticians, from the serious but misguided scientific men who reduce order out of a numerical chaos to the irresponsible compilers of the local newspaper, anxious to boost its own habitat as the unfailing source of mineral, agricultural, or manufactured wealth. This is the season when daily papers publish annual reviews that cover anything from 60 to 170 pages devoted to weirdly inaccurate pictures of wonderful progress and strangely contradictory figures proving—just what they want to prove. Some of the performances are completed a week before the year is ended, as if to emphasize the fact that the editors hate to be harrassed by too many facts. To quote one amateur statistician when

deriding his competitors, their premature New Year's editions are "glaring products of inaccuracy, mendacity, and general slipshod methods." In the end the public gets more smoke than light, and carries away only a general idea of plethoric productiveness, a small share of which each individual hopes will fall into his lap. Another effect is to throw doubt on all statistical statements and to warrant a discounting that reduces their educative value to a minimum.

FROM a brief report issued by Mr. R. D. George, State Geologist of Colorado, we note with pleasure the earnest effort that has been made by him and his assistants to furnish Colorado with geological investigations of practical value. This work was done in the summer of 1908, despite the failure of the Legislature to provide the necessary funds, so that the final reports and maps were delayed in publication. The State Geologist and Mr. R. D. Crawford lent their credit and gave their services to the State, hoping for reimbursement later. It is wholly discreditable to a mining region of such importance that the necessary work of its Survey should be hampered in this petty manner. We congratulate Mr. George on a notable exhibition of public spirit and scientific industry.

A DOPTION of a new process at a new mine is one of the common indiscretions of the novice. He is easily persuaded that the ore is 'rebellious', and the promoter has ready the new-process man with his improved solution of the peculiar metallurgical difficulty as another means of wasting the new investor's money. But it is remarkable that a great corporation such as the Tankanyika Concessions, Limited, should announce officially a program involving methods of copper metallurgy that lack the approving stamp of experience. It appears that the copper deposits at Katanga, in Central Africa, include large quantities of excessively silicious oxidized ore containing as much as 10 per cent copper. It is proposed to treat this class of ore by reducing the copper to the metallic state, followed by mechanical concentration. On a laboratory scale no doubt a process of this kind will yield the metal, but as concentration is practiced today this will entail a loss of 18 to 30 per cent, according to the fineness of the metallic particles. A large part of the metal resulting from the reduction of oxides and carbonates without fusion would undoubtedly exist in a fine state of subdivision. Perhaps the Tanganyika Concessions has developed a feasible process, but the failures attending such attempts elsewhere in the past would hardly recommend experiments of this nature in the heart of Africa. If it be a question of getting something at a profit from otherwise wholly unavailable ores, regardless of the percentage of loss, then as a matter of business it might become warrantable, but the announcement made bears the suspicious appearance of the 'new process', still wanting its Q.E.D. Metallurgical inventions need to be put on probation near at home, where failures will not be damagingly expensive.

The Italian Earthquake.

The calamity that has befallen the communities dwelling on the Straits of Messina has elicited the understanding sympathy of the people of San Francisco. While the earthquake of April, 1906, did less damage than the succeeding conflagration, the terrifying aspects of that mysterious natural disturbance are vividly remembered. With us the damage arose from the complexity of civilized ways of living, whereby the illuminating gas escaping from broken pipes was ignited by the short-circuiting of electric wires thrown out of place, and superadded to this prime factor was the destruction of the water conduits that otherwise would have been instrumental in extinguishing a multiplicity of fires. On the Tyrrhenian coastlands of Italy the loss of life was incomparably greater because the population was congested in badly built dwellings. The ordinary Sicilian house is constructed of boulders loosely held in poor mortar, and it needs but a small earth-jar to bring such walls to the ground. Therefore an earthquake of unusual severity plays dreadful havoc. Whether the estimated loss of life be exaggerated, and whether the dead be numbered by 100,000 or 200,000, it is certain that the destruction of Messina, Reggio, and the neighboring cities constitutes one of the greatest catastrophes of history. If we do not feel the horror of it as much as we might, it is because every day our newspapers devote pages to the sordid details of lesser tragedies; even our sense of the value of human life has been lessened by the frequency of accidents on railroads and in coal mines, on street railways, and in theatre panics. The emotions of the American are jaded with a daily iteration of horrors. All the more, therefore, is it remarkable that the fate of the Italian unfortunates should have awakened such instant sympathy, expressed promptly, by word and deed. More than money or message, the United States offers an asylum for the houseless people of Calabria and Sicily; we shall see a large influx of immigrants from southern Italy. Whether they be welcome or not, their coming will certify to the fact that for the oppressed and unfortunate of every country there is still a land where a new start can be made, and where a new home may be built. That, after all, is the greatest service America can render Italy in this dark hour.

Another phase is presented when we recall the fact that the country devastated during the closing days of 1908 has been the theatre of seismic forces since the dawn of history. Etna has thrown a cloud over the battles of the Punic war, Vesuvius lighted the revels of the Romans, and Stromboli, the lighthouse of the Mediterranean, has been a guide alike to the Greek and to the Latin navigators. The idylls of Theocritus were written among the villages of Sicily; on her plains the Norman and the Saracen fought; in her valleys was grown the wheat that fed Athens and Rome. For twenty-seven centuries this beautiful land has been the dwelling place of the most advanced communities of the old world, despite the fact that it lay close to the edge of a volcano,

and on the vibrating edge of a shifting portion of the earth's crust. Why do men continue to pitch their dwellings in such dangerous places? Because the intervals between great catastrophes are greater than the period of a generation, and therefore rarely befall more than once in the life of an individual. The last big Calabrian earthquake was in 1783, and undoubtedly it was to the well informed Sicilian of today but a remote scientific fact having no direct bearing upon his own happiness. Moreover, men think all men mortal but themselves; if an earthquake come, each expects to survive, and if any house be ruined, it will be his neighbor's. Finally, where Nature is unkind with her left hand, she is generous with her right. The harbor of Messina brought wealth to thousands, and the plains of Sicily enriched generations; they were willing to take the risk in exchange for the advantages offered. And so for a period covering the written record of humanity the wheat of Sicily and the wine of Calabria have been gathered under sunny skies and beside blue waters in defiance of the volcanic ashes that might darken the heavens or the mysterious unrest that might waken the sea to deeds of horror. The harbor of Messina was the haven of the Mediterranean after an earthquake, as before; the bay of San Francisco attracted the shipping of the Pacific before 1906 and after. Geologic forces have not hurt Sicily so much as the clash of armies, Latin and Greek, Roman and Carthaginian, Norman and Saracen. Geologic faults have made less of a rift in San Francisco than the deeper fault of a lost sense of civic decency. We have overcome the effects of the first with triumphant energy and incomparable courage: we still cower under the morally emasculating agencies of an incivism that even the earthquake could not exorcize, that even the fire could not refine.

Revival of Gold Dredging.

Not long ago it seemed as if the application of the dredge to gold mining were destined to be restricted to one or two localities and to enterprises of small proportions. In the south island of New Zealand, in New South Wales, in the upper watershed of the Ovens and its tributaries in Victoria, a number of small dredges were earning a profit for their owners, but the sum total of production and, fortunately, of capital invested was small. These enterprises continue to make fairly satisfactory returns, but taken collectively their yield is hardly equal to that of one big lode mine. In America, the dredges in Montana, in Colorado, in Idaho, and in other Western States have had an encouraging measure of success. In more distant regions, such as Tierra del Fuego, Bolivia, Brazil, Burma, West Africa, and Dutch Guiana the dredge has been digging laboriously and with varying results. In Siberia and in British Columbia dredging enterprises on a large scale have been undertaken, but the profit has been nothing to boast of. Many have been attracted by the supposed absence of risk in dredging because of the certainty with which the ground can be tested, and this supposed certainty has been the excuse for carelessness in prospecting such as would ensure failure

in any form of mining enterprise. Nevertheless, the only region where the dredging industry assumed large dimensions was in California: at Oroville, on the Feather river, first, and subsequently in the valley of the Yuba, near Marysville, and on the American river, near Folsom. These three localities may be grouped as parts of the central California dredging region. At the present time not less than 45 dredges are in operation in this region, producing \$5,500,000 per annum. One of these dredging companies, namely, the Yuba Consolidated, is much the most productive gold mine in California; in fact, it produces as much gold as the two richest lode mines in the State, the North Star and the Kennedy. The Yuba Consolidated has 12 dredges at work, digging 80 feet, of which 58 feet is below water and 12 feet above that level; the gross yield is \$1,650,000 per year, the net profit is \$1,200,000; the gravel yields 21 cents per cubic yard and is worked at a total cost of 5 cents per cubic yard; so that fully 75 per cent of the gold won represents dividends. This is a splendid mine. There are 14 dredges in other parts of California, notably at Redding and at Snelling, from which good returns are expected. Thus there are 59 dredges in California, producing in excess of \$6,000,000 per annum. These facts, now generally known, have stimulated the search for dredgeable ground. Prospecting and testing of alluvial flats have been undertaken in many corners of the world, especially in Alaska and the Yukon. In the North there are 12 dredges digging profitably, including the 7 operated by the Yukon Gold Company at Dawson. On the Stewart, the Forty-Mile, the Solomon, and other rivers near the Arctic Circle a season of four to five months is spent industriously in the extraction of gold from deposits of unusual richness and occurring under exceptional conditions. Next season several new dredges will be started, and if they utilize the experience in method and machinery now available they ought to do well. During the past summer two or three expeditions have been sent to Colombia and the result has been that engineers of established reputation have recommended the construction of dredges to exploit ground already tested systematically with churn-drills. In Siberia several American engineers versed in this branch of mining have found areas suitable for dredging and English-Russian companies are preparing to make a start. Other countries might be specified, but the facts stated suffice to prove a general increase of interest in this branch of mining. It seems warranted. To the younger men of the profession this expansion offers a new field for their energies. The use of the churn-drill in testing alluvial ground and experience in making proper inferences from such bore-holes, have given a valuable tool to the engineer. Drilling affords a method for reliable sampling. Co-operation between the manufacturers of machinery and the men that use it has resulted in the designing of dredges as much stronger and more efficient than the feeble digging-machines of ten years ago as a modern battleship is more powerful than the war-vessel of discarded type. The training of efficient dredge-masters renders it

unnecessary to consign a complicated mechanism to the control of a farmer or of a book-keeper.

In a recent article we referred to the fact that 65 dredges had been built for the North and of these 12 were successful enterprises. To those who think hastily, but not profoundly, this proportion, of about one success to four failures, looks discouraging. As compared to the average result of business enterprise or industrial adventure, the proportion is high. To one who has investigated the conditions under which dredging was applied in the North and the low average of skill available in the efforts as yet made toward overcoming local difficulties, it is astonishing that so many successes should have been won. Assuredly, there is good augury for the future. When operators have learned that careful sampling with drills and shafts is as necessary in dredging as the breaking of assay-samples preliminary to vein mining; when they have been impressed with the fact that cheap machinery is often the most costly; that experienced dredge-masters are essential; that it is as profitable to bite a file as to dredge frozen ground—then the way will be clear for a proportion of success that may be augmented to a beatific maximum.

Financial Confidence.

It is an impressive fact that the annual output of mineral wealth in the United States has reached the magnificent value of two billion dollars. This is double the production of eight years ago. In the same period the value of farm products has increased at a lower rate, the agricultural gain being about 65 per cent. The relation between mineral and agricultural production in a country of imperial dimensions is an intimate one. At bottom the disparity between the two has probably been the chief cause of the rise in prices, so conspicuous a feature of the last decade. Mineral production is the basis of manufacturing; it calls for more workers, and that means more to feed and to clothe. If the supply does not come forth in proportion to the demand, the inevitable result is higher costs of staple necessities; this is at once reflected in the costs of manufactured articles through an advance in wages to meet the expenses of living. Thus also is explained the 'land hunger' which is leading on the one side to pioneer enterprise in undeveloped territory, and on the other to reclamation projects and to more intensive methods of agriculture. Instead of looking to artificial causes for an explanation of the recent financial stringency, or accusing the gold output of responsibility in the case, it is evident that in these simple relations between the primary additions to the world's wealth is found a fundamental reason. Exchange, in the last analysis, is effected on the credit system; gold is only the conventional measure of value, and serves to settle the balances that constitute a trifling fraction of the total volume of business. The enormous areas of land being reclaimed in the South and West, and in Canada, and the great tracts just being opened to colonization in Mexico by the building of railroads, will exercise an important influence in providing means for taking care of

the mineral output of this country at its present high level.

The enormous industrial expansion, which has received a momentary check, began about ten years ago. This is so nearly contemporary with the evolution of electric appliances to a high state of economic efficiency that many have attributed the phenomenal demand for mineral products to the development of this new agent. The world had never before witnessed so large a growth of business; such colossal enterprises had never before been undertaken; nor had mining ever played so large a part in the transactions of capitalists. It became less the sport and more the serious concern of business men. The extended application of electricity was unquestionably an important factor in the expansion of the mineral industry; the call for one metal makes demand for others. No forms of human endeavor stand alone; they are intimately correlated. The advance in electrical appliances was matched by progress in every department of the mechanical arts. In short, the world stood ready, with improved machinery, and more highly perfected methods, to utilize natural resources upon a grander scale. In view of this, the financial depression of the past year is not comparable with those that preceded it. There were new causes operating, and the steady call for metals during 1908 is evidence of an enlarged consuming power. A pronounced feature of the year just ended has been the absolute indifference of the agricultural centres to the prevailing depression. They have been unconscious of its existence; prices of food-stuffs have not receded. This shows that the mineral production had not surpassed the world's need so much as that the conditions of production had grown too costly. The inevitable result is to stimulate agriculture to bring about a truer balance. The *London Economist* index number in June, 1907, was 2601, the highest point reached in 30 years, indicating that the relation between cost of living and earning power was abnormally strained. Under such conditions a reaction was inevitable, and greater conservatism in business would necessarily follow. This is reflected strongly in the diminution of failures by 25 per cent from the previous year. In line with this evidence of conservatism is the reflex of slackened trading shown in the 15 per cent reduction of bank clearings. The lesson to be deduced from the conditions observed in 1908 is that actual over-production of manufactures had not occurred; that the development of natural resources had proceeded at so rapid a pace under the stimulus of improved mechanical facilities as to overtax available supplies of the necessities of life; that artificial governmental interferences with business affairs brought about retaliations unsettling normal business relations, and accentuating distrust; but that the expansion of industry had so enlarged the demand for supplies of every kind as to prevent collapse of enterprise. In fine, business is progressing in a conservative manner, and will continue to progress while the mineral output leads the agricultural, unless overstrain be induced, as happened in 1907.

PERCY L. FEARN has returned to Guatemala from New York.
H. C. CUTLER has returned to Goldfield from Sonora, Mexico.
NICHOLAS J. MARTIN was in San Francisco, on his way from Nicaragua to Seattle.
A. CHESTER THOMAS has returned from New York to Santa Barbara, California.
J. S. WILLIAMS, Jr., is superintendent of the Moctezuma mine, at Nocoziari, in Sonora.
E. NELSON FELL has left London for Colombia, to examine the Frontino & Bolivia mine.
J. GORDON HARDY is now manager of the La Republica mine, near Ocampo, in Chihuahua.
EDWARD H. COOK announces a change of residence from Tucson, Arizona, to El Paso, Texas.
GEORGE A. PACKARD, of Boston, was in San Francisco, and has gone to Shasta county, California.
F. W. RIDLEY has been appointed superintendent of the Allouez and Centennial mines, Michigan.
THOMAS PASCOE, superintendent of the South Mount Boppy mine, New South Wales, is expected in London.
H. S. MUNBOE, of Joliet, Ill., will be at Baca, Distrito del Fuerte, in Sinaloa, Mexico, during January and February.
EDWARD H. NUTTER has resigned as superintendent for the Liberty Bell Gold Mining Co., of Boston and Colorado.
PELHAM V. COOPER, assistant manager of the Black Butte quicksilver mine, Oregon, was in San Francisco for a few days.
F. O. HARVEY has formed a partnership with A. G. B. WILBRAHAM, with offices at No. 2 Laurence Pountney Hill, London.
WILLARD S. MORSE has resigned as metallurgical engineer with the American Smelting & Refining Co., and will reside at Denver.
WILFRED RICKARD, formerly of Wisconsin, is manager of the Victoria Quartz mine, at Bendigo, the deepest gold mine in the world.
ELTON W. WALKER has resigned as superintendent for the Tombstone Con. Mines Co., to take effect on February 1, after which date he will be in consulting practice at Detroit, Michigan.
T. C. CHAMBERLIN, professor of geology in the University of Chicago, accompanied by his son, R. T. CHAMBERLIN, sailed from San Francisco for Japan on January 9, on his way to make a study of the resources of China, in behalf of a special educational commission sent thither by the University of Chicago.

Obituary.

R. H. HARLAND, of Lombard Court, London, died on November 25. He was a well known analyst and assayer, and was intimately connected with the cyanide process.

General Mining News.

ARIZONA.

COCHISE COUNTY.

Duffner Bros. have bonded the Duffner group of claims, between Paradise and Portal, to Homer Prickett and associates, of Douglas, who have already done the assessment work. The consideration is not stated.—The Shattuck-Arizona Co. has resumed active operations and the first shipment of ore to the smelter since November 1907 has been made. The first consignment amounted to four car-loads, or nearly 200 tons. About 60 men are employed and the management expects to mine and ship from 80 to 100 tons per day.—At the new Powell shaft of the Pittsburg & Duluth Mining Co., being sunk on the dividing line of the Hope and Wagner claims, the steam for the hoists will be piped 1350 ft. from the old plant. The equipment consists of two 75-hp. Atlas boilers, a two-drum Hendrie & Bolthoff hoisting engine, a Sullivan air-compressor, oil pumps, and minor equipment. The Pittsburg & Duluth plant will be used for hoisting Powell ores and for this purpose the old head-frame is being re-built.

MOHAVE COUNTY.

A. L. Derbyshire is at Gold Flat preparing to work the Abe Lincoln mine, north of McConnico, upon which he has

Sacramento Shaft of the Copper Queen Mine, at Bisbee.

a bond. A shaft is to be sunk to a depth of 200 ft. at once.—The Yucca Cyanide M. & M. Co. will start work soon upon its San Francisco mine. The new work will be done below the 600-ft. level. W. C. Merry, of Cedar, is assistant superintendent.—Work has been commenced on the Cruz mine, near Cedar, by M. J. Ryan and others, of San Diego. A company has not yet been formed, but exploratory work is undertaken by nine business men of that city. It is the intention of the company to sink a shaft to a depth of several hundred feet. The surface ores were the richest ever taken from a property in that part of Mohave county.

PINAL COUNTY.

In the Ray-Kelvin district conditions are improving daily and the past month has shown a great increase in activities. The Ray Consolidated Copper Co. is pushing its development and prospect work. The Madeline shaft of the Kelvin Calumet Co. has been leased and the Ray company is exploring some of its ground which lies directly in the rear through this shaft. The Ray company at present has eleven large churn-drills at work day and night; four of the machines are Keystone and seven Star, employing about 75 men. There is also other development work being done over a large part of the property. The mill at Kelvin, six miles distant, which has been overhauled and re-modeled,

will be in operation in the near future and will handle 350 tons of ore per day. The plan of the company is to block out the entire property and eventually erect a large plant for treating the ore.—The Christmas Gift mines, near Saddle Mtn., are to be worked by a syndicate of British people, of which Capt. C. E. Birchman of Liverpool is the head. The property was located on Christmas day, 1882, and the company now owning them paid \$200,000 for it.

SANTA CRUZ COUNTY.

The shaft at the Pittsburg mine, in the Santa Rita mountains, is now down almost 200 ft. From the 160-ft. level a cross-cut was run north, striking the vein 18 ft. from the shaft and cutting through 8 ft. of good concentrating copper ore. Sinking was continued and the shaft is now bottomed in ore of a good grade. The showing is so good that T. A. Cox, general manager for the Arizona Pittsburg company, owning the property, has gone to Pittsburg to talk matters over with the directors of the company in regard to putting in heavier machinery.—The Bland Mining Co. will start operations early in the spring on its property in the Harshaw district. W. M. Schwartz, of Kansas City, Missouri, will have charge of the mine. The Bland company is composed of Kansas City people.—The Douglas-Arizona & Sonora Development Co., of which L. M. Raines is president and P. J. McIntyre is treasurer, has purchased from W. M. Murphy and associates and Robert Daly and associates two groups of mining claims adjoining the World's Fair mine, in the Harshaw district. It is understood that the purchasing company will at once do a large amount of development work on these claims, and will employ a good force of men.

YAVAPAI COUNTY.

The Golden Ridge M. & M. Co. is working three groups of claims in the Weaver district and expects to increase the working force on each as soon as the camp accommodations are ready. E. A. Wing, who is general manager, has recently returned from Memphis, Tennessee, where he went to consult with stockholders. It is rumored that the Arizona Copper Belt Co., whose property is south of Constellation, expects to erect a 10-stamp mill.

CALIFORNIA.

NEVADA COUNTY.

(Special Correspondence.)—The Donovan and Torpie & Schroeder claims, in the Rough and Ready district, have been bonded by H. M. Black, representing Eastern capital.—A new 10-stamp mill and centrifugal pump with a capacity of 200 gal. have been installed at the Golden Gate mine. An electric power line will be built to carry a direct current to operate the hoist and pump. A good reserve of milling ore has been developed. W. H. Martin is superintendent.—A 200-ft. shaft has been sunk at the Weeks mine and a 4-ft. body of mineralized ore opened up by cross-cutting at this point. The owners are arranging for a test crushing of 100 tons.—The unwatering of the shaft at the Yuba mine is progressing rapidly, and it is expected to have the lower levels clear within a few more days. This will be the first time in many years that the mine has been free of water. The mill is running one shift on ore from above the 400-ft. level.—At the Grey Eagle, sinking is going on at three different points. Enough ore is being taken out in the course of developments to keep the 10-stamp mill in operation.—The new shaft at the Alaska mine has nearly reached the level of the old workings, and a cross-cut will be driven to connect. As soon as this has been completed, operations on a large scale will be commenced. The turbine pumps are handling the water easily. George St. John is superintendent.—The mill at the Idaho-Maryland is running on good ore from the 500-ft. level. Driving for the vein has commenced on the 1000-ft. level. The drift on the 700-ft. level will be pushed ahead steadily. About seventy men are now employed.—The North Star Mines presented the miners with \$10, and the muckers and carmen with \$5, on Christmas. The other mines provided refreshments for their employees.

Grass Valley, January 2.

SAN BERNARDINO COUNTY.

Some time during the coming week the Oro Belle Mines Co. will increase the force now employed in the north drift of Oro Belle No. 1. Two shifts are to be put on, and the drift continued farther north. Before January 10 the company expects to begin work on its new shaft, which will be sunk 300 ft.—The Atolia tungsten mine, near Johannesburg, has resumed with a large force of miners, and the development work will be pushed with energy. The closing of the mine last fall was due to the condition of the market, tungsten having taken a drop. Since then the price has gradually ascended, and now large profits are again in sight.

SHASTA COUNTY.

The California Consolidated Co. is reported to have cleaned up \$10,000 in their November mill-run at the Gold Ball mine, near Sawyer's Bar.—The two blast-furnaces of the Balaklala smelter have been reinforced the past week by the blowing in of the two converters, and blister copper is now a regular product of the big Coram plant. Little difficulty has been met in the reduction of the Balaklala ore, and such incidental problems as are bound to come up from time to time in the early days of a great plant of this kind are yielding to solution and are being successfully met one after the other.

SIERRA COUNTY.

The gasoline hoist at the No Better shaft, at Forest, is completed and operation will soon be started.—It is rumored that the Finane brothers have bonded their quartz claim near Forest to a company which will develop the ground. This vein is the south extension of the Eureka, and has some good prospects.—The gravel-mill at the Omega mine is steadily working, and is said to crush 75 tons in 24 hours. Adam Keiffer has charge of the mill and J. McCoy runs it on the opposite shift. There are 30 men employed, and as they live at the mine the place resembles a small town.—A few more men were put on at the Telegraph mine this week, and there are now about thirty men there taking out gravel which will be washed when the water starts.

TRINITY COUNTY.

(Special Correspondence.)—The Golden Jubilee mine, six miles above Carrville, is the most important producing property in the northern portion of the county. Lying in the heart of the famous Coffee Creek district, the property has been worked at various times, with varying success, with several years of idleness also marking its career. Under a former management the property was practically worked out, no provision being made to keep developments ahead of mill requirements. Some few years after the closing of the property, due to the causes already indicated, the owners, principally Napa, California, investors, commenced operations on a more modern plan. New levels were run, improvements made to the reduction plant, and every endeavor made to develop a good reserve of ore. That this change in affairs has been uniformly successful is attested by the position that the Golden Jubilee now occupies. The Golden Jubilee vein is apparently characterized by a persistent fissure. The strike is north and south, with an easterly dip of about 70°. On the surface the vein has been traced for 6000 ft. from Boulder creek in a southerly direction. The vein varies from 20 in. to 16 ft., and assays from \$10 to \$40 per ton. The lowest level gives approximately 1000 ft. of backs, with the vein showing about six feet wide at this point. Four upper levels have been driven for considerable distances and have disclosed the vein at several points. From No. 1 level connections have been made with the lower workings by means of a double-compartment shaft. In all, approximately 4000 ft. of drifts have been extended. A new 10-stamp mill has been recently completed and will be placed in commission within a few weeks. It is several hundred feet below the old plant and is so situated that the lowest working level of the mine will be readily accessible. The cyanide plant is large enough to handle the pulp from 20 stamps, as it is intended to increase the capacity of the mill to 20, and possibly 30,

stamps at a comparatively early date. The mill is operated by water-power, approximately 500 miner's inches falling 450 ft. The mill is arranged to handle amalgamating, concentrating, and cyaniding ores. In the case of amalgamation, the pulp will pass from the stamps into a plate-room, but if concentrating ore is being treated the product from the stamps will be run through classifiers and distributed to Wilfley and Frue concentrators. The slime will be discharged into agitators and the gold recovered in cyanide solution. The sand will be conveyed to the cyanide plant and treated separately. In case the sand proves too coarse, it will be first re-ground in the Huntington mills and then passed to the cyanide tanks. The old plant consists of two 3½-ft. Huntington mills and a 20-ton cyanide plant. Although antiquated, this plant will be used as an auxiliary to the new mill, and is expected to be valuable in many ways. Blocks have been set for 20 additional stamps, and it is likely that these will be added in the course of the next two or three years. The property comprises seven claims, and at the present time 65 men are employed. The remoteness of the mine from a railway mitigates against it to a certain extent, inasmuch as it renders the shipping in of supplies and machinery expensive. The sole means of freighting between the railway station of Delta, the nearest commercial point, and the mine, is by means of mule-teams. An abundance of excellent timber and water is found throughout the district, and the climate is good throughout the year, despite the high altitude.

Weaverville, January 1.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—The task of installing the Sigafoos boring machine at the Georgetown adit on Columbian Mtn. is progressing satisfactorily. The grading has all been completed, and now the building for the housing of the machinery is being put together. A greater portion of the machinery has been delivered on the ground, the heaviest piece of which weighs six tons. According to the terms of the contract, the machine must be ready to start by January 11, but it is possible that a few days delay will be experienced, owing to the fact that a pumping plant must be installed on Clear creek. This plant is to be installed at the expense of the Georgetown M. P. & T. T. Co., while other expenses incurred are to be borne by the American Rotary Tunnel Machine Co. It is understood that a large number of mining men from various parts of the State have signified their intention of being present to witness the tests that are to follow.—William Rogers, manager for the Santiago M. & M. Co., announces that he has in contemplation the construction of an aerial tramway which will start at the Santiago mine, in East Argentine, the terminus to be at the company mill in Georgetown. While the total length is not known definitely, as near as can be ascertained the distance will be 3½ miles. With this tram in operation, the vast bodies of ore in the Santiago mine workings can be delivered to market at a reduced cost of from \$2 to \$3 per ton. The various lessees at the property are breaking a heavy tonnage of smelting ore worth more than \$50 per ton in gold, silver, lead, and copper. Especially is this true of the block of ground being operated on the second level by Rogers & Harper, where a body of ore is exposed in the stope that is five feet wide. It has been decided by the management to award no further leases, and as a result more men will be employed on company time.—W. Collins has taken a lease on the upper level of the Wide West, and in sinking a winze, to a depth of 12 ft., a streak of 500-oz. silver ore has been uncovered that is four inches wide. During the last 10 days from five to six sacks have been taken out daily, but as soon as the winze has been put down to the 50-ft. point driving is to be started. There is exposed alongside of the high-grade product a body of mineralized quartz that assays 80 oz. silver per ton. It has been decided to leave this standing, pending a rise in the price of the white metal.—The

Argentine-Montezuma M. & T. Co. has resumed work in the advance of the Vidler adit. A contract has been awarded to William Goetz for the driving of the bore 200 ft., but it is understood that as soon as the work has been completed another contract will be given. The compressor-plant was started last week and the bore is going in at the rate of from six to seven feet per day. The Vidler tunnel on the eastern side of the range has been driven 3800 ft., while on the western side it is in 700 ft. The total distance to be driven is 7300 ft. before an outlet will be furnished for the ores of Summit county. There now remains less than 2800 ft. of ground to be broken before the connection is made.—The Hollingsworth M. Co. was organized this week, with a capitalization of \$100,000. A group of claims on Sherman Mtn. will be developed upon a systematic scale, work having already been put under way. Orlando B. Smith of Silver Plume has been appointed manager.—The compressor for the Linn Con. M. & M. Co. arrived a few days ago, and now a force of men is putting it in place. Electric power will be used from the Two American Sisters plant. The new set of jigs for the concentrating plant has also arrived and is being put in place. Within 10 days everything will be in readiness for treating ore.—Ed. Butts returned this week from an Eastern trip, made in the interest of the Key West group of claims, on Leavenworth Mtn. His mission was entirely satisfactory, and already an active campaign of development has been put under way. It is intended to drive the adit, which is now in 700 ft., for 200 ft., for the intersecting of the Key West vein, which from shaft workings produced high-grade gold and silver-bearing ore.—The reconstruction of the aerial tramway running from the Pelican mill to the Seven-Thirty dumps is nearly completed. This tram will now run to the Pelican dumps, where large quantities of stuff are available that can be handled at a profit. W. A. Hood of Silver Plume is manager.—J. G. Hite has started work upon the Lamont group of claims, situated on Columbia Mtn. The adit, now in 400 ft., is to be driven steadily forward, some ore being in evidence at the present time. Denver capitalists have become interested in the enterprise.—A. B. Montgomery, of Denver, director in the Astor-Stewart M. & M. Co., stated a few days ago that the Western Metals Co. will shortly start work upon a new mill, the process being electrochemical. The plant is to be erected at the East Griffith mine, on Griffith Mtn., and will be fed upon ores from that property exclusively. It is claimed by this process the gold, silver, lead, and copper can be extracted in bullion form. W. D. Hoover, of Denver, is owner of the mine.—It is reported upon good authority that the New-house tunnel people, at Idaho Springs, will shortly start work upon the construction of a 500-ton milling plant. From what can be learned, it is the intention of the company to reserve one-fifth of the capacity for its own ores, while contracts will be entered into with various operators for the milling of the ores. This big bore, which is now in 17,400 ft., is being advanced, contracts having been entered into with the owners of property lying along its course that will necessitate its advance for another 4000 ft. It is a great boon for the district, as already a small army of miners has been given employment. W. H. Collins is manager.—J. J. Culley, manager of the Accord M. & M. Co., this week increased the working force, and within a short time regular shipments of smelting ore will be started. The adit is being driven forward, while driving is in progress upon both the Clyde and Pineo veins.—The Golden Glory T. M. Co. expects to increase the output during the present month from its Drummond mine on Columbian Mtn. Driving is being carried forward, while the winze is being given another lift of 75 ft. Orebodies are exposed in both places and the product mills from \$40 to \$45 per ton in silver and lead. At the Golden Glory adit a force of men is being employed and the bore is being driven steadily forward. It is expected that the extension of the Bellevue-Hudson vein will be reached within 60 ft. J. L. Young, of Lawson, is manager.—F. Percy, of Idaho Springs, this week resumed work upon the Chicago adit holdings, situated up

Chicago creek. The bore will be driven steadily forward, as a large group of claims is controlled.—The Gold Anchor mill, which has been re-modeled, was put into commission this week and from this time forward will be kept running night and day. There are immense bodies of ore exposed throughout the various workings of the mine, all of which can be handled at a profit.

Georgetown, January 2.

LAKE COUNTY.

Steady work has been maintained on the Matchless since the decision of Judge Cavender gave temporary possession of the property to the lessees. Operations are being carried on in the No. 7 shaft, through which the ore is hoisted. A promising streak of silver was opened there some time ago, and the present production is coming in the greater part from this vein. Several carloads can be shipped every week, it is thought, if the work is not further interfered with. Henry B. Stevens, T. M. Raney, and associates are temporarily in possession of the Matchless mining property on Fryer hill as the result of a decision rendered by Judge Cavender in the District Court, but Mrs. Elizabeth Tabor, the owner of the mine, threatens to bring injunction proceedings restraining them from working it, on the claim that they have forfeited their lease by violating their con-

Map of Southwestern Colorado.

tract. The main point involved in the controversy, according to the opinion of Judge Cavender, is the terms of settlement between Mrs. Tabor and the lessees, of the smelter returns. Mrs. Tabor claims that she should be paid her royalty upon the gross smelter returns, while the lessees contend that the lease calls for her royalty, not before the hauling and switching charges have been deducted.—Work on the Progressive property, which was opened under a new set of lessees during the early part of last week, is reported to be more than favorable. The old shaft has been almost completely drained. A good plant of machinery has been placed in commission. Work through the old drifts of the mine will be taken up at once. It is figured that the first ore shipments will be made before long.—About 20 men are now employed on the A. Y. & Minnie property, in California gulch. Shipping was started last week. The output goes to the chemical works in Denver. The work of cleaning up some of the drifts is not yet complete, and as soon as they are made ready, the working force of the mine will be increased. It is expected that the property will be running in full blast within two weeks.—Thomas F. Gilroy and associates, who are sinking a new shaft on the Across the Ocean group, in Big Evans gulch, have reached a depth of 50 ft. Progress is necessarily slow, as they are in hard ground. The property is below the Penn and Big Six mines and in territory which is considered valuable.

SAN JUAN COUNTY.

The Mogul company is working a force of six men in prospecting on the group of claims above Gladstone owned by the late W. A. Walter. These claims were held for many years by Mr. Walter, who did a great deal of work and had good prospects. The Mogul company is operating them under a bond and is earnestly pushing the work to find the orebodies which the property is thought to possess.—The Des Ouray, which lies in Poughkeepsie gulch, along the line between San Juan and Ouray counties, is to be worked as actively as circumstances will permit throughout the winter. A body of ore was cut some months ago in running a cross-cut from the main development adit.—The San Antonio is well in the lead as the greatest shipper of crude ore in the entire San Juan for the year 1908. The season's shipments from the San Antonio since the railroad was opened to Red Mountain in the latter part of June, until the end of December, will number 200 cars—approximately 5000 tons of crude ore—of a net smelter returns value of about \$100,000. This is a remarkable showing for a mine only in its second year; two years ago it was only a little prospect hole with but 35 ft. of development work.

TELLER COUNTY.

The year's output of the Cripple Creek district is estimated to be \$16,230,525, representing a tonnage of 770,978. The maximum month's production was in August, when the tonnage was 68,886. The production for 1908 exceeds that of 1907 by \$3,155,533. The average value of all ore from the district was approximately \$21.—The Blue Diamond Mines Co., owning approximately 123 acres of patented properties in different sections of the district, has leased its Waterloo claim, on Ironclad hill, for a long term to Curtis J. Smith, president and general manager of the Michorado Gold Mining Co., owning the Seven-Thirty claim adjoining. A deep shaft is being sunk near the dividing line between the two properties, and both will be developed therefrom. Applications for leases on other holdings of the company have been filed with the secretary and will be acted on at the next meeting of the directors, to be held early in the month.—Work will be resumed on the Rose Nichol Gold Mining Co.'s group of fractional claims, containing 10 acres in a solid tract on Battle mountain and Bull hill. Charles S. Walden, the well known mining man of Victor, has formed a new leasing company to operate this group, and the lease from the company will be dated January 1. The main shaft on the Rose Nichol group has been sunk to a depth of 600 ft., and in excess of 3500 ft. of lateral drifts and cross-cuts have been carried in the development of the mine, which has produced to date approximately \$12,000.—Operations have been resumed after six years of inactivity, by the Cripple Creek Land & Mining Co., owning a large acreage north of and adjacent to the corporate boundary of Cripple Creek. A shaft is being sunk from the surface on the Emma Palmer placer. A depth of 20 ft. has been reached and an electric hoist is to be shortly installed. In an old discovery shaft, sunk in the gulch several years ago, now caved and filled with mud and refuse, a strong vein was exposed at bedrock. W. F. Burns, who is manager of the owning corporation, is authority for the statement that ore from this vein gave returns of \$16 gold and as high as 105 oz. silver per ton. The new shaft is to be carried to a depth of 100 ft. before lateral work is attempted, but at this depth a cross-cut will be carried over to the discovery vein.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence.)—The most significant feature of mining in the Coeur d'Alene throughout the past week has been the formal opening of the Idaho-Northern railroad December 30. The opening was the occasion for a great celebration throughout the whole of the North Side, and special trains were run from both Wallace and Spokane over the new line. It is expected that both regular freight and passenger trains will be put on the line by the middle of January.—The Bear Top Mining Co., operating one of

the biggest and most extensively developed properties on the North side, is advertising for bids for 460 ft. of raise, to connect the No. 2 and 3 levels, and putting the mine in a position to commence shipments of ore as soon as the railroad facilities will permit. It is estimated that there is \$360,000 of shipping and \$200,000 of concentrating ore in sight at the present time. The mine is fully equipped with all necessary machinery and a water-driven concentrator of 100 tons capacity.—The stockholders of the Charles Dickens Mining Co. have no longer any interest in the property. The time allowed them for turning in their stock in the old company and receiving an equal number of shares in the Idaho-Knickerbocker Mines Co., in consideration of a payment of seven cents per share, has expired, and, as far as can be learned, in this district very few of the holders appear to have taken advantage of this offer. The only means by which the stockholders in the old company can regain the property, which was sold to A. D. Gritman under a sheriff's sale, would appear to be by means of a voluntary assessment to meet the indebtedness of the company to Mr. Gritman within one year. A meeting of the Idaho-Knickerbocker Co. has been called for next week, when the terms under which the new company will acquire the property from Mr. Gritman will be discussed.—A contract for 200 ft. of driving and cross-cutting has been let on the property of the Horn Silver Mining Co. It is expected that a depth of 400 ft. on the vein will be attained. It is the intention of the company to erect a concentrator in the spring, and nearly all of the funds necessary for this purpose have been secured.—Samples taken from the face of the drift in the 50-ft. level of the Josephine mine, on which a good strike of ore was recently made, and where the vein has been proved to be about 12 ft. wide, give returns of \$66 per ton, made up as follows: gold, \$1; silver, \$4; copper, \$18; and lead, \$43. Machinery for further sinking has been ordered. It is also the intention of the management to drive a raise to the surface, a distance of 65 ft. on the dip of the vein.—It is believed that the Morning mine, the big producer of the Federal company in the Mullan district, is to be equipped with a hoist similar to that in use at the Hecla mine at Burke, which was installed last winter at a cost of about \$50,000. Engineers of the Federal company have been examining the plant at the Hecla mine and gathering data on its work. The hoist has a capacity of 2400 ft. for a lift of three tons of ore on one trip, and is driven by electricity. The manufacturers are the Westinghouse Electric & Manufacturing Co. of Pittsburgh and the Wellman-Seaver-Morgan Co., of Cleveland.—According to statements issued by Morris H. Hayman and Edward Baer, of New York City, president and secretary, respectively, of the Golden Chest mine, in the Murray district, extensive improvements are to be made in that property this spring. It is the intention of the management to increase the capacity of the 20-stamp mill by the addition of another 30 stamps, and to install the necessary machinery for the extraction of tungsten. Advances have been made to the management for the tungsten output of the mine by both the United States Government and the Krupp steel works of Germany. It is believed that as much as \$900 per ton can be gained from this ore. The company has also under consideration the advisability of installing a cyanide plant.—A large amount of machinery is about to be installed at the Butte & Coeur d'Alene mine, on which a big strike of ore was made some time ago. The new equipment will consist of a four-drill compressor, a compressed-air hoist, electric light plant, and other machinery. The company proposes to both sink and raise on the ore-shoot and to make regular shipments of the ore extracted during development. J. E. Quinlan, of Mullan, is president.—The estimated production of the Hecla mine at Burke for 1908 is 282,800 oz. silver and 9,928,130 lb. lead, as compared with 550,342 oz. silver and 19,024,893 lb. lead for 1907. The decrease for the present year is due to the fact that the mine was closed from January 1 to June 1. A force of men is now sinking a shaft from the 900 to the 1200 ft. level.—From two to four feet of ore carrying

gray copper, lead, and carbonates of iron has been exposed in the property of the Rainbow M. & M. Co. The adit has been driven about 550 ft., but 100 ft. more is necessary to get under the surface showing. The men in the lower workings have been taken to the surface and are engaged in the exploration of the upper workings.—The spring development of the Nipsic mine, operating the famous Father Lode claim, will include the letting of a contract for 100 ft. of work on the No. 3 level and the construction of a wagon road to Dobson's pass, together with a tramway to the railroad in Nine Mile canyon. A large quantity of ore is sacked and ready for shipment.—Active development has been resumed on the property of the Acme Mining Co., north of the Snowstorm mine. A contract for the continuation of the adit for 100 ft. has been let, and as soon as this has been completed another will be let.—The management of the Tucker M. & M. Co. has let a contract for 100 ft. of work to H. O. Dahl and others. The adit has been driven 450 ft., and it is believed that the present contract will be enough to tap the vein at an approximate depth of 350 ft. It is the intention to install a four-drill compressor in the early spring and to enlarge all the company's buildings, with a view to engaging a large force of men.—The Hecla mine at Burke has declared a dividend at the rate of three cents per share. This involves the distribution of \$30,000, and is the 66th dividend paid by the company. A total of \$190,000 has been paid this year, and a grand total of \$1,710,000.—A dividend of $1\frac{1}{2}\%$ has been declared on the common stock of the Federal Mining & Smelting Co. This is the first dividend on the common stock since this time last year. The total paid on the common stock since the incorporation of the company is \$2,643,750, while on the \$20,000,000 of preferred stock the company has disbursed this year \$630,000, and a total in all of \$3,934,250. It is believed that the declaration of this dividend has a considerable amount of significance for the stockholders of not only the Federal company itself, but for the stockholders of the American Smelters Securities Co. and the stockholders of the American Smelting & Refining Co. According to the rumors, the Securities company has not been earning its dividends, and has been forced to borrow from its parent. If this be so, the \$45,000 which it will receive January 15 on Federal stock will help materially to cut this indebtedness. Should the Federal company be in a position to increase its common dividends, it will go far toward liquidating the entire amount. The Federal company has on hand about \$1,000,000 in cash, practically all of which may be considered as working capital, the liabilities, with the exception of its stock, being only small current items.

Wallace, January 2.

NEVADA.

CHURCHILL COUNTY.

The sampler of the Western Ore Purchasing Co. at Hazen was destroyed by fire on the night of January 3. The blaze originated in the oil-burner used under the boilers. Insurance to the amount of \$35,000 was carried on the plant. The business of the company will not be interrupted, as it owns the old Nevada Ore Sampling Works, at the same place, and that property will be used pending the re-building of the destroyed structure.

ESMERALDA COUNTY.

W. E. F. Deal, of San Francisco, has purchased, at Sheriff's sale, a group of mining properties at Candelaria, including the Holmes and Northern Belle. The consideration was \$201,419. It is believed that the new ownership will mean a resumption of activities at this long abandoned camp.—More than half of the 100 stamps in the mill of the Consolidated company are now dropping regularly in the actual treatment of ore, and are working without a hitch. The number will be gradually increased until the entire battery is in operation, which it is believed will be accomplished early next week.—The Combined Mining & Leasing Co. has secured a new 18 months' lease on their old block of ground on the Velvet, beginning January 1, and work has

been started in earnest once more, a contract having been let for 200 ft. of cross-cutting. The recent strike on the Ricker lease, adjoining the Combined lease on the west, has given a new impetus to the work.—A discovery of rich ore at a new camp called Wilson has caused a small stampede from Goldfield, Tonopah, and near-by camps. The find was made by J. W. Wilson, on a claim on which he had been doing the assessment work. Numerous leases have been granted and a townsite is being planned.—The re-organized Johnnie Consolidated, of which Al. D. Myers is president and general manager, started up its mill recently. Twelve out of the 16 stamps are now in operation, and the rest will be put in commission as soon as the machinery is all tested.

LINCOLN COUNTY.

The Milwaukee group of claims, near Pioche, has been bonded to William C. Alexander and his Indiana associates, and development work is to be started at once.—The Pioche X-Ray Co. has ordered a compressor-plant for use in driving the adit on its property in the Highland district. The bore has 400 ft. more to go before cutting the vein. J. W. Taylor is general manager.—The Metals Exploration

Eastern Nevada and Western Utah.

Co., which recently took over the Point mine of the Pioche-Nevada Consolidated Mining Co., has completed several new mine buildings, including a boarding-house, bunk-house, and office. A force of miners, under Thomas J. Hooper as superintendent, is driving both ways on the 65-ft. level, the purpose being to decide on the proper place in which to start the working shaft.—The Nevada-Des Moines has ordered a 40-hp. boiler and sinking pump and will resume sinking in its shaft at Pioche.—William M. Wantland, of Salt Lake, has purchased the Weston group of claims, which lies between the Pioche King and the Abe Lincoln, at Pioche. He will organize a company to work it at once.

WHITE PINE COUNTY.

The Giroux smelter, at Ely, was destroyed by fire the last week in December. The building is a total loss, while equipment was damaged but not destroyed. The plant was completed last summer, but was not blown in, and hence the loss does not interfere with the continuous operations of the Giroux property.—The construction of the third reverberatory furnace is progressing satisfactorily, and the fourth unit of the big plant will be completed by the time it is needed. The Veteran mines and the Giroux are employing all the men who apply for work, and all Ely mines are producing average outputs.—The Kohinur Mining Co. has been incorporated by C. E. Millick and associates, of Osceola, Nevada. The purpose of the company is to erect a mill and install a mining plant at its property just across the range east from the Nevada Consolidated smelter. The ore is said to average \$17 per ton. It is reported that Portland, Oregon, capital is back of this enterprise.

Special Correspondence.

LONDON.

Venture Corporation. — Poderosa in Chile. — Developments on the Rand. — Public Indifference. — Consolidations.

One of the most interesting flotations of the year is the Poderosa Mining Co., Ltd., which has been formed to acquire the assets of a company of similar name registered in Chile. The present flotation is not so much for the purpose of buying out the present owners or raising new capital as for the purpose of transferring the proprietorship from Chile to England, and thus making a market for the shares. The mines are in the district of Collahuasi, Tarapaca, and have been connected by a new branch line with the Antofagasta railway. Developments were started in 1903 and regular shipments of ore began in January, 1908. To the end of October 17,256 tons of ore averaging 25% copper and 11 oz. silver per ton have been shipped. The profits for 1908 are estimated to have been sufficient to pay for the whole of the cost of machinery and plant and to pay £60,000 as dividends. The success that has attended the development of this mine is chiefly due to the mining and civil engineering skill of Robert Hawxhurst, Jr., who is well known in San Francisco.

Some important economic developments have been taking place in the Rand during the last six months or more, as has been mentioned from time to time by your Johannesburg correspondent. The curious part of it is that the news relating to these matters is not circulated to any great extent in London, and the interest taken in them seems to be mostly academic. The public in general is not attracted by any of these improvements in the conditions of Transvaal mining operations; this seems a pity, for there have been many more unattractive opportunities for getting a decent return on capital invested than the schemes put forward just at present. Briefly, these improvements have been caused by the plentiful supply of native labor to take the place of coolies, by the consolidation of organizations operating groups of mines, and by the lowering of working costs all round. Many low-grade properties that have been lying neglected for years are being taken in hand, and in many of the more developed or older properties it has been possible to count the blocks of hitherto useless low-grade ore as useful reserves. An example of the indifference of the public was the failure to float the consolidated company to take over the Randfontein group, but Sir Joseph Robinson, the controller, nothing daunted by the coolness of investors, has come forward with a million pounds wherewith to effect the organization.

I mentioned some months ago an example of the consolidation of the East Rand Proprietary and its subsidiaries. This week an equally important amalgamation has been announced by the Crown Reef people.

With regard to the raising of additional funds by mining companies during the past year, it is hardly necessary to say that the stress of circumstances has forced many of the controlling houses to remodel their views as to what expenditure should be charged to capital and what to revenue. It has been the orthodox rule in many quarters to issue new shares for new plants. Owing to the inability of shareholders recently to take up new shares, the issuing houses have had no alternative but to provide for these additional expenditures out of revenue.

In the domain of big public companies that undertake the promotion of mining enterprises, the most interesting event of the year has been the re-organization of the Venture Corporation. For eight years this company financed on a razor-edge, without issuing a report or calling a meeting of shareholders, in itself a truly wonderful performance; however, everything comes to an end at last, including the hidden troubles of this company, and accordingly a re-construction, with the subscription of new capital, was effected during the summer. Another interesting feature in the same connection is the broadening of its basis of

operations by the Consolidated Gold Fields of South Africa. Originally intended for financing mines in the Transvaal, this company has in recent years gone farther afield. During the last few weeks it has been announced that the company is intending to put additional money into some of the West African mines, and accordingly general attention has once more been directed to that part of the world.

NEW YORK.

American Smelters. — Statement by Daniel Guggenheim. — New Competitive Company. — Anthracite Coal Reserves. — Newhouse Mines.

Recent events in New York mining circles are likely to have an important bearing upon the American copper industries. It will be remembered that, since the panic of 1907, the shares of the American Smelting & Refining Co. advanced on the New York Stock Exchange erratically. All kinds of rumors have been started by the news bureaus operating in the interests of powerful financiers, and many of Mr. Lawson's advertisements in the daily press have referred to them. The public has been led to believe that the control of the company passed from the Guggenheims to the Standard Oil group during the panic, and that it was to be annexed to the Amalgamated Copper Co. On the strength of these assertions the stock of American Smelters advanced. Early in December, however, the information was given out in Wall Street, that very few shares in the company are held in the names of either the Guggenheims or Rockefellers. Many shares are in the company's books in the names of Wall Street firms as trustees for the owners. The Standard Oil insiders were reported to have sold out their holdings in November. The result of these statements was a marked fall in the stock. Contemporaneously with this decline, the public was informed that the Standard Oil had again quarreled with the Guggenheims, and had determined to establish a rival concern, which would erect smelting plants wherever the American Smelting & Refining Co. has them.

A prominent news bureau, identified with Amalgamated Copper interests, gave out the following:

"The Rockefellers have sold out all of their holdings in the American Smelting & Refining Co., and have taken stock in a new combination. A smelters' war of big proportions appears imminent.

"The copper companies have been for years dissatisfied with the charges of the smelting monopoly, but the breaking point came about a year ago, when the Utah Consolidated Co. was unable to get a definite answer to a proposition to the Guggenheims for the renewal of its smelting contract. The Utah company then began the erection of an independent smelter, which will be ready for operation in the spring."

These statements were published by several of the New York dailies and aroused much comment in mining circles. The following day, Daniel Guggenheim, president of the American Smelting & Refining Co., issued the following statement:

"There is nothing new that I can see, or any change of policy, in the so-called Ryan-Cole development of the copper smelting business. The group of gentlemen known as the Ryan-Cole, and their following, have been for many years in the copper mining and copper smelting business. They are great believers, undoubtedly, in copper as a metal. So am I. They can see that a great deal of money can be made in this business, as can be when intelligently prosecuted.

"They have interests in copper smelters and copper mines in various parts of the United States, and properties in various parts of the world. It is a business they have gone into, and whether or not they have now formed a large company for the purpose of taking in other interests, or for the purpose of building new smelters and buying new mines, it is nothing new, nor is it anything that the American Smelting & Refining Co.'s shareholders need look upon with any concern whatsoever, because the American Smelting & Refining Co. has not a single exclusive copper smelter in the United States. They have a few copper furnaces at

some of their plants, which are simply used as auxiliary furnaces to provide for by-products and such ores as are contiguous to their locality.

"The American Smelters Securities Co. has only one exclusive copper smelter in the United States. Neither of these companies is likely to have in the near future any more exclusive copper smelters, because they look upon copper smelting as an extremely annoying business, and if one is fond of litigation and likes it as a steady diet I strongly recommend building a copper smelter in a farming locality.

"The American Smelting & Refining Co. is largely interested in copper refining. I personally am very fond of, and believe in, copper mining as a highly profitable business, and copper refining as a very satisfactory business; but I would not go into the copper commission smelting business or advise any companies with which I am connected to go into the copper smelting business unless to smelt the copper ores from their own mines. By that I mean I do not believe that the smelting of copper ores on commission for others is a business that, at present at least, is desirable. If one has copper mines and a smelter situated away from the farming district to treat the ores of those mines, this is an entirely different affair.

"As regards the lead-smelting business of the American Smelting & Refining Co.: Fully 90% of all the lead ores of the United States and in the Republic of Mexico are now controlled by ownership of mines and by long-time contracts. These ores are either controlled by the American Smelting & Refining Co. or by its present competitors. And I wish to state further that the earnings of the smelting company at the present time, as well as of the Securities company, are considerably in excess of the dividends that are being paid."

On December 21, a corporation, called the International Smelting & Refining Co., was registered under the laws of New Jersey, at Trenton, N. J. This company was incorporated with a capital of \$50,000,000, and its object, as stated in the incorporation papers, was to engage in the business of mining, milling, and smelting ores.

While the above events were occurring, meetings were held in the offices of Phelps, Dodge & Co., in New York, and attended by representatives of all the large American and Mexican copper producing companies, including representatives of the Amalgamated and A. S. & R. companies, with a view to reaching an agreement for improving copper mining conditions. The results of these meetings are officially reported to have been satisfactory. While disclaiming any trust agreement, James Douglas, who presided at the meetings, stated that they were merely a repetition of a series called five years ago by the late John Stanton. All the prominent copper producers were asked to furnish their output-statistics, so that the amount of copper can be easily and properly ascertained at any time. This was agreed to by the producers, and in the future each company will be informed of the production of the others. This is the official account of the agreement reached.

There is a strong impression in mining circles, however, that within the past three months a powerful copper trust has been formed in New York by interests closely connected with the Standard Oil and the United States Steel corporations. The trust will practically control the mining and smelting of American and Mexican copper ores, as well as the leading concerns manufacturing copper goods. It promises to have a greater control of the copper industries than the United States Steel Corporation has of the steel industries. It appears probable that the International Smelting & Refining Co. will be used to manage the Trust. It will be found later, doubtless, that instead of the Rockefeller interests being at war with the Guggenheims, they have absorbed them, as they have absorbed many smaller producers. The copper market is not expected to feel the influence of the new combine until early in the summer months. The price of copper will then start to advance, and within two years high prices are predicted for the metal.

William Griffiths, a coal expert, in giving evidence at the Coal Trust hearing in Philadelphia last week, stated that he estimates the available supply of anthracite in the United States to be about 22,000,000,000 tons. The latest estimates made by M. R. Campbell for the United States Geological Survey were 21,000,000,000 tons. P. W. Shaeffer, in 1879, estimated the supply at 26,360,576,000 tons for anthracite, and 8,276,856,666 tons for steam coal in Pennsylvania. A study of these estimates will show that the question of the exhaustion of the coal beds will not interest the present generation. Other witnesses at the hearing testified that the railroad companies either directly or indirectly controlled 96% of the coal lands of Pennsylvania and adjacent State. Most of the land was acquired by purchase nearly forty years ago.

Robert S. Bradley, chairman of directors of the American Agricultural & Chemical Co., and David A. Ritchie, president of Lamb & Ritchie, sheet metal manufacturers, Cambridge, Mass., have been elected directors in the United States Smelting, Refining & Mining Co. It is officially stated that the earnings of the Newhouse Mines & Smelting Co. are not sufficient at present to justify the payment of dividends. The company is earning enough to pay its fixed charges, and a surplus which is going to the improvement account. There is a large amount of ore blocked out in the mine which can be profitably worked when copper again reaches 18 cents per pound. The present output is 800,000 lb. of copper monthly, but the plant now being erected will have a capacity of from 12,000,000 to 15,000,000 lb. of ore. It is estimated that the copper in the ore already blocked in the mine amounts to 2,000,000 lb. Stocks on hand amount to 200,000 lb. The Boston Consolidated mine is producing 3000 tons of ore daily. A new plant, which will increase the capacity 45%, is in course of erection. It will be completed in February, 1909.

Reports from Michigan state that there is at present no accumulation of copper in the Lake Superior district. Navigation is closed and the docks are quite cleared. Railroad shipments to New York and Boston have been commenced, and it is not proposed to allow any copper stocks to accumulate during the winter. The United States Circuit Court at Trenton, N. J., on December 19 dissolved the order to show cause for restraining the receivers of the Arizona Smelting Co. from the delivery of deeds for the property. Everything is now arranged for the receivers to convey the properties of the Arizona Smelting Co. and of the Consolidated Arizona Smelting Co. to a new corporation. Hooley, Larnard & Co., of the New York Stock Exchange, have been appointed reorganization managers. They announce that the reorganization plans contemplate the formation of a new company to acquire, subject to an existing indebtedness of \$255,000, the properties purchased at the trustees' sale on November 10 last. The new company will issue 1,840,000 shares of stock of a par value of \$5 each, and \$1,200,000, 30-yr., 5% bonds, convertible at any time into stock at par. Each two shares of the old stock, on which an assessment of 50c. per share shall have been paid, will be exchangeable for one share of the new stock, and bonds at par to the amount of the assessment paid. Notes of the old company will be satisfied with 5% cash, 85 in stock, and 10 in bonds at par. The company would thus resume business free from debt and with cash on hand of approximately \$797,775.

The Old Dominion Copper Mining Co. is expected to close the year 1908 with a December production of 4,000,000 lb. copper. Six furnaces have been running full time this month. The total production for the year is estimated at 38,000,000 lb. The directors of the American Zinc Co. propose issuing new debenture bonds, amounting to \$5,000,000. All the shareholders on the company's books on December 22, between that date and January 1, 1909, will have the right to subscribe for the bonds in the proportion of one \$1000 bond for each \$4000 per value of stock held. Underwriters have agreed to take all the bonds not issued to stockholders in the company. The debentures are being issued to enable the company's plants to be enlarged.

MEXICO.

Review of Conditions in 1908.—Progress Under Difficulties. — New Enterprises in Chihuahua. — Operations in Sonora. — Cyanide Process at Zacatecas. — Smelting in Durango. — Guanajuato.

Quiet but not unsuccessful; thus may the condition of the mining and metallurgical industries of Mexico for the past twelve months briefly be summarized. As mining is nearly the most important basis of enterprise in the country, and decidedly so considered in its international aspects, the year 1908 did not open auspiciously for this Republic. The falling metal markets, the financial troubles in the United States, and practically the entire cessation of the inflow of foreign capital, did not promise a bright future. Added to the setback that would naturally occur was the threatened increase in freight rate of 10, 20, and 30%, respectively, on ores of a valuation under \$25, from \$25 to \$50, and over \$50 per ton, and though it has not yet gone into effect it has hung throughout the year like a black cloud over the head of the miner, who would have had to carry the burden. What that burden would amount to may be imagined when it is stated that a close estimate shows that 48% of the freight receipts of the Mexican railroads are from mining products and supplies. After six months of worry came the publication of the project for revision of the mining

western part of Chihuahua, but some of the prospecting concessions held by the Greene company will expire early in January, and it is expected that many new people may be drawn to the district. East of the city of Chihuahua the Chihuahua Copper Co. is opening a large property in the Chorreros mountains; good zinc continues to be developed near Picachos; and close to Presidio del Norte prospecting and development of the oilfields by Hearst and Keene has led to the organization of a large independent company reputed to have \$10,000,000 capital, which will persist in the thorough prospecting of all eastern Chihuahua, where a large concession is held. Both eastern and western Chihuahua are greatly encouraged by the building of the Kansas City, Mexico & Orient railroad, which is spreading out in both directions as rapidly as its funds will permit. At Terrazas, about 30 miles north of the city of Chihuahua, the little old copper smelter of the Rio Tinto company, together with its mines, was taken over by Corrigan & McKinney, of Cleveland, Ohio, and the smelter has been almost wholly re-built and enlarged to a capacity of 300 tons per diem. It will be blown in early in January. Just outside of Chihuahua, at Morse, the new plant of the American Smelting & Refining Co. has been completed and three furnaces are in operation, being supplied principally with low-grade ores from the company's mines in Santa Eulalia. This plant is producing a carload of lead bullion

The Esperanza Mill and Mine, El Oro.

law, placing restrictions on foreign operators in Mexico. Though the greater part of the objectionable features were eliminated from the final draft of the law before presentation to Congress, the effect was to check new enterprises. A slight uneasiness was also felt by an increase in the tariff on iron and steel, and their manufactures, but of greater importance has been the recent move on the part of the railroads and the domestic coal producers, for an increased freight rate, or a protective tariff on imported coal and coke. This is still under consideration by the Government commission. From all sides, during the entire year, there has been a continual nagging at the heels of the miner. Though it has in truth been a quiet year, yet progress has been made, and about thirty of the principal companies have paid in dividends \$8,500,000 gold on a total capitalization of \$60,000,000. Perhaps the most marked progress has been in the State of Chihuahua. In the great old camp of Santa Eulalia the production has continued without interruption at the rate of 12,000 to 15,000 tons per month, and important discoveries have been reported from the Mina Vieja, the Velardeña, the Santander, and the San Toy group. In western Chihuahua the year has seen the completion of the mills and the placing on a good paying basis of the Republica and Rio de Plata companies, with an electric plant at the latter; the building of a large portion of the mill at the Lluvia de Oro, as well as its 500-kw. hydro-electric plant; and the enlargement of the mill and the completion of hydro-electric power plant for the Dolores Mines Co. All of these are using the cyanide process. Rich and important strikes have been made in Yoquívó and Uruachic. The total collapse of the Greene Gold-Silver Co. and its allied companies has been a serious detriment to the

per day. An aerial tramway is being erected by the A. S. & R. Co. for carrying ores from the mines to the Mineral railroad for transmission to the smelter. The Encinillas smelter, at Santa Rosalia, has undergone considerable alteration and addition, but still remains closed. In the Parral and Santa Barbara districts, the Tecolotes of the American Smelters Securities Co. has had a most successful year, treating 18,000 tons per month of the complex lead-zinc-iron sulphides in its re-constructed mill; El Rayo Mining & Milling Co. has been developed into a great property, and as it yields principally gold, it has not been materially affected by the metal prices; the San Francisco del Oro has given the flotation and the Sutton-Steele dry-table processes thorough tests, but without success, and the mill is now closed; the famous Palmillo of Pedro Alvarado, has been taken over by Boston capital under a 15-year lease, and will be systematically developed below water-level as soon as an adequate pumping plant may be installed. West of Parral, at Roncesvalles, a number of rich strikes were made.

In the State of Sonora affairs have been perhaps more quiet than in the other important mining States, owing to its principal producers being copper properties that have suffered from the unsatisfactory condition of the copper market. The Greene-Cananea, however, resumed operations in July with an almost entirely new smelting plant of 3000 tons daily capacity. This resumption was urged by the Federal Government, that aided the company by granting a concession for the free importation of fuel oil from Texas. At Nacozari, the Moctezuma company, controlled by Phelps, Dodge & Co., completed the 2000-ton concentrator in April, and the same is now in operation. The

Cumpas and the Belén mining companies have each established small copper smelters on their properties in the interior of Sonora. El Tigre (or the Lucky Tiger) has been developed into one of the largest gold mines in the Republic.

Zacatecas is to be congratulated on the signs of progress there. Frequent reference has been made in these letters to what has been done in the old camps of Guanajuato and Pachuca, and at El Oro, with the cyanide process. Attention has been called to similar possibilities with that process at Zacatecas, with its thousands of tons of low-grade dumps. To the El Bote Mining Co. may now be given the credit of being the pioneer in introducing into Zacatecas the cyanide process on a large scale, where it has replaced amalgamation and lixiviation. As was the case in Guanajuato and Pachuca, others will soon follow.

In the State of Durango the year has seen the completion of many improvements at the smelting plant of the Peñoles Mining Co., at Mapimí, and that of the American Smelters Securities Co. (leased to the American Smelting & Refining Co.) at Velardeña. Both are in operation. There also appears to be likelihood of the old Durango Iron & Steel Co., owning the famous iron mountain—El Cerro del Mercado—resuming operations, after a shut-down of some 8 years.

In Guanajuato some new properties have been opened, and additions and improvements have been made in the established mines and mills; and the efficiency of sliming and filtering has been proved at the Pastita, the San Francisco mill of the Guanajuato Consolidated M. & M. Co., raising the total extraction to about 97%. The same method has been adopted by several other companies. The mills now operating in the Guanajuato district have a total of 580 stamps and 13 tube-mills, and are treating 60,000 tons per month. In addition, there is an output of 12,000 tons per month of shipping ore. The total monthly production has a value of nearly \$1,250,000. Among the most important works initiated in 1907 was the drainage tunnel, Porfirio Díaz, that has just been completed. The Mexican Central railroad is running its trains into Guanajuato, and the Mineral Belt railroad, while not completed, is furnishing a much needed railroad and switching service to many of the properties.

The State of Jalisco has made rapid strides in the western portion. Near Ayutla the Agua Blanca has been developed into an immense low-grade copper property, and has a 100-ton mill; in Ayutla the Carrizo Copper Co. has completed an 80-ton smelter and is ready for operation. At Etzatlan the Amparo Mining Co. has proved the success of cyanidation and is obtaining good returns from its ores. In the Hostotipaquillo district the largest success has been attained. Here at least a dozen different companies have pushed development work in all parts of this complex cross-veined system, and no failure is recorded. Late in the year the Marcus Daly Estate acquired claims in the district, and in the coming year aid will be given by the rapidly approaching Southern Pacific railroad between Guadalajara and Guaymas.

At El Oro, the Esperanza, Dos Estrellas, and El Oro continue their remarkable production, with a combined monthly profit of over \$300,000 from 60,000 tons of ore. An English company is working on the Victoria in the hope of finding the vein lost in the adjoining Dos Estrellas workings.

Pachuca has added to the list of properties using the cyanide process, and the Real del Monte, the pioneer in using cyanide in that district, declared its first dividend of \$100 per share on 2550 shares in March.

In Oaxaca the smelting situation has not improved, and both plants are idle. Important prospecting is being carried on by the Oaxaca Coal & Iron Co. with promise of success. A number of the important mines have had a good year, others have resumed operation, and at the Ocotes mine of the Tezuitlan Copper Co., extensive development has opened large orebodies. The smelting plant of the latter company at Tezuitlan, in Puebla, has been closed down since November, 1907, for the purpose of enlargement.

KALGOORLIE, WESTERN AUSTRALIA.

Renewed Labor Troubles.—Discoveries on the Golden Mile. — Perseverance and Kalgurli Developments.—Great Boulder Reserves.

It would seem as if we were to have a repetition of the recent trouble with the firewood employees. So far, about 500 men are on strike from the Kurrawang Firewood Co., demanding more money for handling the fuel. The great trouble is that nearly all the workers are foreigners, and early this week they adopted a menacing attitude, necessitating the despatch of a posse of mounted and foot police to protect loyal workers and the property. At this writing, the position of affairs is far from being quiet.

The past month has been characterized by many good developments, and a buoyant share-market has resulted. Among the group of small mines at the south end of the 'Golden Mile'—the Boulder Main Reef, Chaffers, and Hannan's Star—much interest has been taken. Parties of tributors some time ago opened good ore in the Chaffers lease, and continue to get returns up to \$60 per ton. The Hannan's Star also cut the continuation of this lode, and conditions in the Boulder Main Reef are rather encouraging.

In the Perseverance mine, at 1750 ft., high-grade telluride ore was found early in the month, and there was an unseemly rush to get shares, which appreciated considerably. So far, however, the output has not risen at all. The Kalgurli found good ore in new ground at the 100-ft. level, and at 1500 ft. in the Horseshoe the east branch of No. 2 lode was cut, being 5 ft. wide with \$5 assays.

The ore reserves in the Great Boulder are now estimated at 701,165 tons, worth \$17 per ton, this being an increase of 50,000 tons since the end of 1907. Another ball-mill is at work in the Great Boulder plant, this making 4 No. 8 Krupp and 12 Griffin mills; following these are 12 Edwards' tilting type, 2 Edwards' duplex, and 8 Merton roasting furnaces, 22 grinding-pans, 18 ordinary agitators for treatment of the mill-pulp, 13 filter-presses, and 10 Ridgway vacuum machines. The re-treatment of the old dumps by mixing, agitation, and filter-pressing, at the rate of 11,000 tons monthly, has been suspended of late, owing to some metallurgical difficulty experienced in the largest of the tailing heaps.

The October returns were as follows:

Name.	Tonnage.	Output.	Profit.	Dividend.
Associated Gold Mines.	10,437	\$112,000	\$ 40,000

GUANAJUATO, MEXICO.

La Luz. — Guanajuato Development. — 1000-Ton Mill Projected.— Guanajuato Amalgamated. — San Cayetano Mines. — Benito Juarez.—Dos Estrellas.—San Rafael Mill, Pachuca.

La Luz district, 10 miles southwesterly from Guanajuato, is attracting attention by reason of present and prospective operations and the building of the La Luz branch railroad by the Mexican Milling & Transportation Co. This is one of the subsidiaries of the Guanajuato Development Co., that also plans a main line from the Central yards at Guanajuato to the Pinguico, Peregrina, and Santa Rosa mines.

The La Luz branch is in course of construction. It starts from the Central yards and passes close to the San Prospero mill, winds over the hills above the San Cayetano to the Bolañitas group at La Luz, making a line 14 miles long. The track will cross the Santa Ana river over a dam that is to be constructed athwart that stream. The allied companies of the Guanajuato Development Co. have five mills in operation in the district, comprising the Pinguico of 40 stamps, the Peregrina of 100, the San Prospero of 40, Nayal of 20, and the Central of 15 stamps. The San Prospero is operated as a custom plant, treating 150 tons per day by concentration and cyanidation. Close to the San Prospero is the same company's new plant, designed for treating concentrate by cyanidation. It has tanks for mechanical agitation, tube-mills which pulverize to 200 mesh, Pachuca tanks in which agitation occurs in cyanide solution. The material from the latter is forced by centrifugal pumps to filter presses, and through these the solution passes to zinc-boxes in the precipitation room. It is probable that the Merrill precipitation presses, involving the use of zinc-dust as a precipitant, may be installed. L. D. Mills, representing C. W. Merrill of San Francisco, has been making tests at the San Prospero plant, and reports satisfactory results. The new plant is to cyanide the concentrate made by the four or five other mills of the subsidiary companies, thus avoiding the expense of shipping and treatment charges at smel-

crushers which reduce the ore to $\frac{3}{4}$ -in. size before it is carried by belt-conveyor to the battery-bins. There are 100 stamps of 1050 lb. each, installed in two rows, back-to-back. The capacity is 300 tons per day through 40-mesh screens. Amalgamating plates have been discarded and the pulp now passes from the batteries to three Dorr classifiers; the sand from these passes to 10 Wilfley tables, the tailing from the

San Rafael Mill, Pachuca.

ters. One of the main purposes of Mr. Mills is to aid in determining the methods to be employed in the proposed 1000-ton mill, which is one of the projects under consideration by the Mexican Milling & Transportation Co. This milling project is closely allied to the district railroad scheme of the company, the intention being to haul the ores of Pinguico, Peregrina, Santa Rosa, La Luz, and other widely separated mines to a central milling plant which can treat them at a low cost per ton. The low price of silver and the predominance of that metal in these ores make it essential to reduce costs to the minimum. The La Luz ore, however, is proportionally higher in gold than most other ores of the district. One point claimed by those who would use zinc-dust and Merrill presses is that the cost of zinc would thus be reduced one-half and the time required for precipitation would be much shortened.

The Guanajuato Amalgamated Mines Co. is working the La Luz and Plateros veins, near the town of La Luz. It has a main shaft 185 metres deep, surmounted by a modern electric hoist. A level runs 100 metres from the bottom of this shaft to the top of an inclined shaft which extends 200 metres from that level on the dip of the vein. An electric hoist is installed at the incline. There are working levels from the 100, 145, 185, and 250-metre stations, most of the ore coming from the lower levels. The ore is hoisted in cars and dumped into bins at the mill. Here are three Gates

Brown-Pachuca Tanks, La Union Mill.

latter being re-concentrated on another group of 10 Wilfley tables. The concentrate thus made contains 38% iron, and assays ₧120 silver and ₧350 gold per ton, the concentration ratio being 45 to 1. The final table-tailing passes to sand

Mill of Mexico Mines of El Oro.

tanks, in which it is cyanided by a 0.5% KCy solution, with an average treatment of 12 days. Before passing to the sand tanks, however, this tailing goes to sand collectors with rim overflow, the slime discharging to settling cones and then to the slime plant. The slime from the Dorr classifiers passes to de-watering cones, dividing it into 4 parts of water to 1 part of thickened slime. This is charged to conical bottomed treatment tanks, and given air agitation

From these the solution is decanted and passed to the zinc-boxes. A 90-leaf Butters filter-press has been purchased and will soon be installed to treat the solution from the slime plant after agitation. The plant has 26 sand-tanks, each of 90 tons capacity, and 20 slime-tanks, each of 15 tons capacity. The sand-tanks are filled by belt-conveyors and discharged into cars by hand-shoveling. The ore has a silicious gangue, but with a small percentage of lime. C. A. Lantz is mill superintendent, with Wm. Northgraves as superintendent of the mine. The water for mill-work is pumped two miles through a 5-in. pipe to a reservoir above the mill, making an ascent of 600 ft. in two miles. Lawrence Adams is general manager of the property.

The San Cayetano Mines, Ltd., controlled by New York people, and locally managed by F. H. Clark, has the group of mining properties between Guanajuato and La Luz which formerly belonged to the Mexican Mines Association of London. The former owners drove a level three kilometres long on the San Antonio vein, starting in a deep gulch where the old mill and other buildings are situated, and running toward La Luz. This level opened bonanza ore in the early days, and it is claimed that the present management has opened orebodies on the same vein by adits driven from higher points. The ore assays 350 grams silver and 5 gm. gold. The most interesting work now in progress is that of making a raise of 100 metres from the old adit level, 3 kilometres from the portal, to unwater the workings of the Mexia Mora, San Pedro, and Purísima mines. The first named belongs to the San Cayetano and the last two belong to the Guanajuato Reduction & Mines Co. By raising 20 metres farther a connection will be made that will drain all these old workings through the San Cayetano adit. They are embarrassed by caving ground and the work is dangerous.

The Benito Juarez Mines Co., in the State of San Luis Potosí, operating at Piñon Blanco, 10 miles south of Salinas station, has sunk its Eduwigis shaft to a depth of 500 ft. By driving a cross-cut 18 metres from the bottom a strong flow of water was opened, making the installation of pumps necessary before doing any further work. Triplex Aldrich electric pumps made at Allentown, Pa., are now being installed; these will be electrically operated. The mine-water is to be used in the mill. A new 75-hp. double-drum electric hoist has been erected. The mill will be ready for business by January 15. It has 20 stamps, of 1050 lb. each, to have a 7-in. drop, 102 drops per minute. The screens are 30 mesh, and the crushing will be in a weak cyanide solution. Following the batteries are cone-classifiers, Wilfley tables, and an Allis-Chalmers tube-mill. The pulp from the tube-mill will be passed through a Dorr classifier to separate sand from slime, the sand passing to leaching tanks and the slime to cone-bottomed agitating-tanks. The ore is said to be mainly gold, the bullion containing only 30% silver. The gold is free, but is in finely divided particles, and the silver is present as bromide. At the greatest depth, however, the silver exists as sulphide. The gangue consists of quartz and calcite. John C. Brennan and E. P. Ryan are directing the work. The company has installed an electric power plant at Salinas, the generators being run by steam-power, oil being used as the fuel under the boilers.

The Cia. Minera las Dos Estrellas, at El Oro, for the first eleven months of 1908, treated 144,413 metric tons of ore at its No. 1 mill, and 166,532 metric tons at its No. 2 mill. The production of mill No. 1 was 1,504,850 kg. of gold and 15,119,513 kg. of silver; that of mill No. 2 was 1,674,963 kg. of gold and 11,059,785 kg. of silver. The gold production of both mills yielded \$4,292,747, and the silver was valued at \$785,378, making a total of \$5,078,126 for the eleven months ending November 30. Mill No. 1 is the old plant, which has 130 stamps; the new plant has 120 stamps.

The Esperanza's oxidized ore comes from the San Rafael vein and its numerous branches. The sulphide ore comes from a vein parallel to the San Rafael, occurring in the slate hanging wall of the latter. The oxidized ore contains about 90% silica, 3 to 4% iron, and carries $\frac{1}{2}$ oz. gold and 3 oz. silver per ton. The sulphide vein has a width of

5 to 30 ft., the ore assaying 2 to 6 oz. gold and 20 to 50 oz. silver per ton. The oxide and sulphide ores are milled separately, the former passing from the stamp batteries to the cyanide plant, in which the sand and slime are treated separately; the sulphide ore goes from the batteries to Huntington mills, thence to Wilfley tables, making a high-grade concentrate that is shipped to the Aguascalientes smelter, the table-tailing being cyanided. The plant is treating 120 tons per day of the sulphide ore and 300 tons of the oxide. This relates to the work of the old plant; but a new cyanide plant is being erected and important changes are being made which will result in discarding all of the old plant except the batteries, Huntington mills, and Wilfley tables. Concrete blocks are to be built under the stamp batteries, Huntington mills and concentrating tables, all of which will be accomplished without entirely shutting down. The new cyanide plant, under construction, will have 10 Krupp tube-mills, 12 Pachuca agitating tanks, 15 ft. diam. by 45 ft. deep; three Merrill presses for fine sand and two for the slime; and two Merrill precipitating presses. The new plant is situated on a site considerably lower than the old mill-dump. The dump contains half a million tons of material, and the intention is to treat the sulphide and oxidized ores as they come from the mine, and add to them about 300 tons per day from the mill-dump. The new plant, including the re-constructed part of the old mill, will be ready for operation next May.

The north shaft of the mine is 1440 ft. deep. It is sunk in the foot-wall of the San Rafael vein, and is being equipped with new skips. This shaft will be used exclusively for hoisting ore from all the veins; the south shaft, 990 ft. deep, will be used for men and timbers. The operating staff consists of Cortlandt E. Palmer, consulting engineer; Charles Hoyle, general manager; R. A. Conrads, assistant manager; D. L. H. Forbes, superintendent of construction; P. A. Herivel, mill superintendent.

In melting the precipitate at the El Oro plant crucibles of new design will be tried. They are made of graphite, and will have double the capacity of the No. 400 that has been in use. The new type is 29½ in. high, 22 in. diam. at the top, 18¼ in. diam. at the bottom, and 25½ in. at the middle. In the same mill they are using lumps of quartz in the tube-mills instead of the imported pebbles. The 9 tube-mills require 25 tons of this quartz per day, the consumption of the pebbles having been 6 tons per day. The use of the hard quartz instead of the pebbles effects an important reduction in expenses of operating.

The San Rafael mill at Pachuca is about complete, and it is expected to be in operation in January. It is equipped with 60 stamps, 40 of which weigh 900 lb. and twenty 1250 lb. The ore is crushed through a 20-mesh No. 28 wire screen, in a weak cyanide solution, the pulp passing to classifying cones, the coarse product going to Wilfley tables and the fine to pulp-thickeners. The table-tailing is classified in Dorr machines; the sand from the latter, after being pulverized to 200-mesh in tube-mills, goes to the agitating-tanks, which also receive the slime from the Dorr thickeners. The agitating tanks in this mill are the Pachuca tanks (Brown patent), cone-bottomed, air-lift style, giving continuous agitation and circulation of the pulp, affording aeration at the same time. The pulp after agitation is transferred partly by gravity and partly by pumping to 3 pulp-storage tanks, in which it is kept from settling and packing by slow-moving mechanical agitators, which also at the same time provide an even flowing pulp for the Moore filter-tanks. The Moore filter installation consists of two independent units of 100 leaves each. The capacity of the mill is about 300 tons of ore daily. Zinc shavings are used for precipitation. Edmundo Girault is manager of the San Rafael mine and mill; J. B. Empson, lately of Guanajuato, is consulting metallurgist. The ore and dump material to be milled will average about 700 gm. silver and 2 gm. gold per ton. The concentrate and high-grade ore will be shipped to one of the Monterrey smelters. The mine paid dividends of \$1,000,000 in 1907 from high-grade ore that was shipped.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Gold-saving on the dredges at Oroville, under the best conditions, is estimated to reach 85 per cent.

In dredging, labor usually represents less than 40% of the total operating cost; where power is high, the proportion declines to 30%. In ordinary mining, labor constitutes from 55 to 60% of the entire cost of winning the gold.

Prospecting in frozen ground that is shallow is done with a single 'steam-point'. The ground around the 'point' will thaw sufficiently to permit the prospector to sink a hole 3 ft. diam. with a short-handle shovel to a depth of 15 or 16 feet.

To separate iron from manganese pyridine may be added to FeCl_3 solution containing free HCl , which precipitates the $\text{Fe}_2(\text{OH})_6$ completely. Mn under these conditions will not readily oxidize so as to be precipitated. Ni and Co are not precipitated. Al, Cr, and Zn are only imperfectly precipitated.

The Great Boulder Proprietary, the deepest mine at Kalgoorlie, Western Australia, is now 2350 ft. deep. On the 2250-ft. level a lode 5 ft. wide is yielding 29 dwt. gold per ton, the total working cost being a little over 5 dwt., or 20 shillings per ton. Three-ton skips are in use on the main or Edwards shaft, which is vertical.

Radium emanation 'degrades' copper into lithium when the copper is in solution, and perhaps causes the 'degradation' of copper even into potassium and sodium. This was ascertained by Sir William Ramsay. The likelihood of some similar action of radium on gold was freely expressed a few months ago. It now appears that it is easy to exaggerate the transmuting power of radium. E. P. Perman announces that radium bromide will not convert the one-hundred millionth part of its weight of copper into lithium per day when acting under the most favorable conditions, and similarly that it will not convert the one two-hundred millionth part of its weight of gold into lithium per day. No fresh proof has been adduced that any 'degradation' at all is effected by radium.

Elevators for raising wet pulp, such as the tailing from stamp-mills, can be run at a belt speed of 9 ft. per second, and satisfactory results can be obtained at 4 ft. per second. The higher the speed, the better the discharge from the top, but the more strain upon the belt and buckets, if the material is scooped from the boot, so that with the high speed it becomes desirable that as much material as possible be delivered into the buckets, instead of into the boot. A good inclination for a belt of this type is 22° from the vertical. Both head and tail sheaves should be large, the former so that there is more grip on the pulley and less liability to slip, the latter so that the surface of the pulp in the boot may be a good distance away

from the bearings. In estimating the capacity of an elevator, it is not safe to count on the buckets carrying more than one-third their full capacity.

In adjusting surveying instruments be careful not to strain the screws. It is a mistake to imagine that an instrument remains in adjustment longer if the screws be tightened beyond the point required for a snug fit. In this connection it may be well to remember that the adjustments should not be changed more frequently than is absolutely necessary. It is better to manipulate the instrument so as to eliminate slight errors of adjustment than to depend entirely upon correct relations of the fundamental lines. Test the instrument frequently for accuracy of adjustments, but before changing the screws determine precisely, by repeated trial, the amount of error, and remember that an instrument is rarely in absolute adjustment throughout. The same precaution as to straining should be observed regarding leveling screws. If one pair turns too hard, loosen the other pair, and never tighten the foot-screws so much that they can not be easily turned.

Lands below the line of ordinary high tide are not 'public lands' in the sense that they may be located under the placer mining laws, with the exception of such lands in a portion of Alaska. For Alaska, Congress passed a special act that provides for mining beach or tide-lands. By the common law, the title and dominion of all the lands below high-water mark were vested in the King. The common law of England upon this subject became the law of this country, except as modified by subsequent State or Federal enactment. The Supreme Court of the United States has decided many times that the title and dominion of the tide-waters and the lands under them, bordering on its territories, are held by the United States for the benefit of the whole people and "in trust for the future States." Upon the admission of any State into the Union, absolute property in, and dominion and sovereignty over, all soils under the tide-waters bordering such State, passed to it, with the consequent right to dispose of the title to any part of said soils, in such manner as it might deem proper, subject only to the paramount right of navigation over such waters, which is under the control of the Federal Government. This question of ownership of lands below the line of high tide has arisen in California in connection with boring for oil in the ocean off the coast of Santa Barbara county. The State Supreme Court held that an owner of land abutting on the ocean, could prevent interference with his right of access to the ocean, by the acquisition of tide-lands beyond. The Secretary of War had granted a so-called permit, as was done in the early history of Nome, Alaska, but the Court held that "this at most was only a statement that, so far as the War Department was concerned, it would make no objection if navigation was not interfered with." Of course, as to lands bordering on the ocean above high-water mark, and which are still a part of the public domain, title may be acquired under the placer mining laws, provided such lands are valuable for the mineral they contain.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Metric Equivalents.

The Editor:

Sir—Referring to a discrepancy between the equivalent of the metre in English measure, as given on pages 225 and 233, respectively, of our 'Civil Engineer's Pocket-Book':

On page 225 the value is given as..... 3.280869 ft.

On page 233 the value is given as..... 3.28083 ft.

Difference 0.000039 ft.

Concerning this, I quote as follows from page 217: "The determination of the equivalent of the metre in English measure is a very difficult matter. . . . The United States Coast Survey (Appendix No. 22 to Report of 1876, p. 6) adopts, as the length of the metre, at 62° Fahrenheit, the value determined by Capt. A. R. Clarke and Col. Sir Henry James at the office of the British Ordnance Survey, in 1866, namely, 39.370432 in. (= 3.2808666 ft. = 1.0936222 yd.); but the lawful equivalent, established by Congress, is 39.37 in. (= 3.28083 ft. = 1.093611 yd.). This value is as accurate as any that can be deduced from existing data."

In preparing our conversion tables (which include p. 233), we took, as a basis, the 'lawful equivalent', 39.37 in. = 3.28083 ft.; (See table A, 'Fundamental Equivalents', p. 230). The table on p. 225 is an older one, based upon other determinations. The difference, between the two values, 0.000039 ft., = 0.000468 in., is apparently well within the inevitable differences in determination of such a matter, so that both values may be said to be right, and either one of them, so far as we know, as nearly right as the other. It seems to us, therefore, that, in view of the explanation quoted above from p. 217, it is scarcely worth while to make a change in either value as printed.

JOHN C. TRAUTWINE, JR.

Philadelphia, December 9.

The Engineer as a Financier.

The Editor:

Sir—On my return to New York, after an absence of practically three months, I have looked over some of the copies of your paper which I had not seen during my absence, and note with interest your copy of October 17, containing Mr. Hammond's speech as President of the Institute, and your editorial comment thereon.

This speech of Mr. Hammond's, together with your own opinion on the subject, contain the first public expressions by engineers of prominence on the subjects that the Mining and Metallurgical Society of America proposes to discuss, with a view to arriving at the real views of representative mining engineers upon these subjects, and while the Society has not reached the point of actually taking up the matters discussed

by Mr. Hammond and yourself, I believe a large number of the members are preparing themselves for such a discussion.

Candidly, I think Mr. Hammond has rather the better of the argument. He takes a view that a mining engineer's work is essentially commercial work, and that its value is simply commercial. He seems to assume that a man's standing in the profession is not to be determined by anything except his personal character, and in this respect his standing as a professional man is gained, in the same way that his standing as any other kind of a man would be gained; that the value of his work is a question of the value of such work to his clients, who may or may not be able to judge his technical qualifications.

In your editorial, on the other hand, you let the inference be made that a man's work as a professional engineer should be quite divorced from his ideas as a business or financial man. It seems hardly probable that you really intended such a meaning. Let us take for example an outline of a purely technical report on a coal mine. Mr. Smith, engineer, might say something as follows: "I have examined Mr. Jones' farm of 160 acres in Washington county, Pennsylvania. I find such and such openings and such and such drill-holes. I estimate that the coal seam on the farm will average 5 ft. 9¾ in. thick, and that the average analysis of the coal is 60% fixed carbon and 10% ash, etc.," with various elaborations and statements of the same kind. Now let me ask what use is such a report to the average business man, whether he is a technical coal man or not.

Let us then suppose that Mr. Brown, another engineer, gets the same information as Mr. Smith, and adds to it his knowledge of business and makes a report that reads something as follows: "Jones' farm of 160 acres can be depended on, in my judgment, to produce a million tons of coal, which can be mined for \$1 per ton and can be sold for \$1.25 per ton. It can be worked out in 10 years, at a total profit of \$250,000. I figure its present value at \$125,000."

As I take it, Mr. Hammond believes that a competent engineer should be able to make the latter kind of a report, and I agree with him.

As to an engineer investing in stocks or speculating in them, it seems to me that his activities in that direction should be no more limited than those of any other man of common sense. As an index of his character, his investments show nothing except by their success or failure, and by their nature. If an engineer trades on margins and makes or loses his money in that way, he should be classed as a gambler, just as any other citizen would be. If he is successful, he is a good gambler; if he is unsuccessful, a poor one; and one's confidence in him would necessarily be effected by one's estimate of him as a gambler, just as much as on his accomplishments as an engineer. As a matter of fact, a man of ability and stability is a composite character, neither abnormally reckless nor abnormally conservative, not altogether a gambler and not altogether unwilling to take legitimate risks. One can never find out what risks are legitimate and what are not legitimate until he stu-

dies the subject and gains his ideas from experience. Speaking as a man of very moderate success and attainments, I should say that the average engineer should be encouraged to invest his money and take his chances in his own line of business, rather than to keep out of it. I did not buy a share of stock in mining companies until I had been ten years out of college. Now, I think I should have made some investment of that kind the first year I was out. I should probably have lost my money, but I could do that just as well and better with \$100 when I was 20 than I could with \$1000 when I was 30, and a man must gain his experience somehow. He must have his attention called to necessary facts and conditions in such a way that he will give them the attention that they require, and it is seldom indeed that a man gives matters real attention until he deals with actualities. A man with natural bent for financial affairs cannot be kept from making financial ventures by any code of ethics, whether he is an engineer or not, but the man who is an engineer and who deals with financial questions should have some experience as a financier, or else he must be content to let other people draw all the business conclusions that his work warrants, and he must pay them to do it. The way he pays them is by getting less money for his services.

There is no business that is free from speculation and risk. The farmer is just as much of a gambler as any other kind of a business man. The only thing he is sure of is that he owns his land. Every year he takes his chances on a dozen different dangers that may destroy his crops; the conservative farmer, in order to hedge on some of his risks, plants a variety of crops, hoping that the enemy that destroys one may not reach the others. Mining too has its great speculative features, but they are of a different kind—fundamentally different. The miner gambles a certain amount of his money on his ability to find ore, but if the ore is there, it is not subject to any vagaries of the weather—it is always there—and for getting it out and making a profit on it he depends on conditions much more stable than those with which the farmer deals. The mining engineer, to be really competent, must face and master these facts. He is a very poor one if he does not.

I should not like to see it written in any code of ethics, or understood in any unwritten code, that a mining engineer should not be free to take a contingent fee. Granting that the doctor who makes a business of advertising that he will take pay only when he makes a cure, is a quack; and that the lawyer whose business is to take small cases on contingent fees, is apt to be a blackmailer and a shyster; and that the mining engineer who makes a business of reporting on properties to get paid only in the event of a sale, is apt to be a crook, we must nevertheless admit that these persons are so adjudged only because they undertake habitually what to an honest man would be an exceptional occurrence. I would not blame the doctor for wishing to get paid if his patient could afford to pay him but might not be able to pay unless he were cured; nor would I blame a lawyer for interesting himself in a case for

which his client might not adequately be able to pay him unless he won; nor would I absolutely prohibit a mining engineer from taking his pay in shares of a property whose owners might not be able adequately to pay him in any other way and at the same time take care of their requirements. Nevertheless, this circumstance can only be an occasional one, and one's character is a guarantee whether the proceeding is honest or dishonest.

Now, regarding the duties of a mining engineer in the case of apex litigation, it seems evident that this is a case made important, not by the character of the profession, but by the character of the laws. Of course, the laws are absurd; but on that account it is not any more desirable that honest and competent men should leave their clients to deal with dishonest and incompetent men. It would indeed be better that expert witnesses should be appointed impartially by the Court, but that provision has not been made by the law, and it is not the custom; therefore the mining engineer must do the best he can. Since the basic principle on which these cases are fought is a wrong one, and an absurd one, it cannot be denied that thousands of mistakes and inaccuracies have been made in trying to make the best of it. It often happens that the competent man is led, after a week's investigation, to give his opinion on questions that might legitimately take him a year to answer, but he may not be aware of the fact, and makes blunders innocently.

The principal thing to be insisted upon in this connection, as in any other connection, is that a man should try to tell the truth, and should try to secure time for making a proper investigation as to what the truth is.

Smelter Smoke.

The Editor:

Sir—The editorial in your issue of December 19 on 'Smelter Smoke' is exceedingly timely, and should be spread, not only among the mining people, who are naturally your subscribers, but also among the farming communities adjoining the smelting centres, to endeavor to enlighten them on the subject, which they now can view only through the distorted lens of their own selfish interests. The case that lately arose between the Federal Government and the Washoe smelter seems particularly aggravated, in as much as the matter has been heard by a Master in Chancery, and by him reported to the U. S. Court, and a provisional finding in favor of the smelting company made. In this hearing it was shown that the damage done is now small and not, as stated, irremediable, and it may readily be adjusted by appraisement. It is well known that the Washoe plant has put in operation one of the largest dust-chambers, smoke-flues, and chimneys in existence, and that from this they take large amounts of arsenic, letting practically none escape. At the plant of this same company at Great Falls, Montana, similar improvements, costing nearly a million dollars, are now being completed. These evidences of good faith

in the desire to abate possible nuisance should weigh heavily in the balance against mere statements of damage, past and future.

As for the irremediable damage from the smoke and fume, I would like to call your attention to the country around the old copper smelting plant at Spenceville, where several hundred thousand tons of pyritic ore were roasted in heaps. This method is well known as being the most deadly to the surrounding vegetation, yet today, after the lapse of about 12 or 14 years, there is no sign on the surrounding hills of the former de-forestation.

Unfortunately, the entire trend of modern smelter-construction has been toward the concentration of all the gases, from roasting, reverberatory, and blast-furnaces, into one great flue and stack, instead of into several stacks, as in the older practice. This one great modern stack therefore emits a vast volume of gases, of greater concentration, and this, driven by shifting winds, and owing to its great density not being readily dispersed by them, descends like a flail and lays low the vegetation on the particular spot which it touches. In the older plants the sulphurous gases were delivered into the atmosphere at lesser altitudes, but through the orifices of many stacks, and therefore in more dilute form; therefore the effect on the country surrounding the plant could not be as deadly as that from the big stack.

In Utah the copper smelting plants have been closed down by injunctions of court, and two at least will not be re-opened at the old locations; I believe this situation might have been relieved by the installation of the roasting furnaces near the mines, either in Bingham canyon itself or on the bench just outside the canyon; in either case the gases from the roasting of the ores would have been delivered into the air at an elevation of 1800 ft. above the valley, and at a distance of 10 miles or more from it, and would have been harmless. This roasting operation would have removed four-fifths of the sulphur. As an offset to this operation the fact is well known that the smelting of cold roasted material is a much more expensive process than if the same material is transported to the smelting furnace while yet hot from the roasters. The financial equation can be readily calculated, for the respective properties, taking into account the erection of the necessary new roasting plant, as against the re-erection of the entire works at some new point. The works of the Tennessee Copper Co., and of the Mountain Copper Co., have each been equipped with a sulphuric acid manufacturing plant, and the product will be made serviceable in the shape of phosphates. Each of these plants is so situated that it has access to the market for these products, and also has readily available the crude phosphates from which they are made, but these conditions do not exist in most localities where the smelting industry is now established, and the freights on both products would be in many cases prohibitive.

The lead smelting plant of the United States company at Bingham Junction has recently been equipped with a bag-house, and in conjunction with this a patented method of neutralizing the sulphurous acid by means of zinc-oxide has been in-

stalled; this is said to be cheap and efficient, but its applicability to copper smelting plants is doubtful, owing to the vast amount of sulphurous acid gas emitted. There is, however, a mechanical method by the use of which the copper smelting plants, even with their enormous amounts of gas, may hope to reduce the sulphurous contents to a point where they will be practically harmless, and come within the limits prescribed by the courts. This mechanical method may be applied to existing plants, and its operation can be made practically automatic, that is to say, it can be regulated and operated by men of slight experience. The discharge of electricity of high potential through the gases is also being applied, the resulting precipitated dust and acid being claimed as an economy through recovery of by-products, though I do not hear that this method is claimed to reduce the sulphurous acid to sulphuric acid. It is to be hoped that with better understanding of the situation, with the application of known remedies, and the invention of new ones, this question will be solved without the necessity of giving the smelting industry a blow similar to that administered to the hydraulic mining industry many years ago. Your editorial is all right; get it re-printed.

JAS. W. NEILL.

Lead Acetate in Cyanidation.

The Editor:

Sir—I should like to call the attention of other cyanide workers, especially of those using lead acetate in their work, to a case where, in a mill in charge of the writer several years ago, litharge was substituted for that salt, to good advantage. The material being treated was a concentrated tailing re-ground to pass 50 mesh, the greater part of the slime being removed before treatment by agitation in vats 20 by 20 ft. Thus the material agitated was largely fine sand, containing much pyrrhotite and a little arsenopyrite and chalcopyrite. The stirring action was very strong.

Soluble sulphides formed during treatment required the addition of at least $2\frac{1}{2}$ lb. lead acetate per ton of solids in the charge. As this formed a heavy item of expense, William Magenau, the chemist of the mill, experimented with other lead salts and found that litharge, added to the charge in the proportion of $1\frac{1}{2}$ lb. per ton, was equally effective. As lithargé cost only half as much as acetate, it effected a reduction in cost for this item to 30% of the former figure. Besides, it was easier to use, simply requiring to be weighed and sifted into the agitating charge.

This substitution may not be generally applicable, nor in some cases even possible, but it has occurred to me that it might be used to advantage in tube-mill work, adding the litharge with the feed. This would be the logical place to add the litharge when grinding in tube-mills with cyanide solution, which, in my opinion, is likely to be the practice of the near future.

C. M. EYE.

Taracol, Korea, November 26.

PROTECTION OF INVESTORS.

The Mining and Metallurgical Society of America suggested the following questions for discussion among members:

1. What are the essential items of information which should be contained in mine reports for the full protection of investors?

2. How may mining companies be compelled to give such necessary items of information?

3. How often should such reports be published—monthly, quarterly, or annually?

The Pacific Coast section of the Society has held two meetings, at which these questions have been ventilated: the first was on November 21 and the second on December 19, 1908. The following transcript of the discussion will prove of general interest.

T. B. Comstock.—(Communication to the Secretary.)—First, in reports of active mining companies intended for perusal by average stockholders, itemizing is a ready means of observing results. Those who may require the details of operations should always have easy access to such information, and no harm can come ordinarily from publishing this widely. But a knowledge of certain facts is necessary to a clear understanding of the conditions of a business at any given stage. The form of statement demanded by law from National Banks is a good model for financial operations, although it is not, in every respect, what might be desired by individual stockholders.

Mining and metallurgical establishments are not so simply operated, and the status of their affairs demands more flexibility in accounting. The great desideratum in summary mine accounts is the utmost possible generalization without sacrifice of perspicuity. Ordinarily, it is sufficient, for instance, to lump all improvements, without specifying the relative costs of buildings, machinery, and other items. But it is important to make clear distinction between capital accounts and those affecting current loss and gain. Simple statements of actual resources and liabilities give all that is requisite, in the first instance, for determining the real financial standing of the company. However, it is rarely the case that, as with the banks, mining companies hold assets in such really tangible forms as currency and amply secured paper. There should be some recognized method of reporting mine resources in a manner to justify the estimates. The best and simplest procedure for this purpose would be the following of the financial statements with maps of workings and authenticated measurements and valuation of ore-reserves, accompanied with segregated costs of operation, based on a definite unit of quantity (as the ton of ore) and on output within the capacity of available plant.

Such details as cost of candles, explosives, labor, pumping, drilling, etc., are valuable, as statistics, and are necessary for capable and economical administration. But their appearance in administrative reports is generally indefensible. They tend often to confuse rather than to elucidate the actual condition of the business. Whenever, for exceptional reasons, this information may appear to be required, it

is seldom necessary, in such reports, to give more than the general results, such as total average of costs per ton of all or a given part of the composites. Of greater significance is the very desirable comparison of results, period by period. Thus, if it appear that total costs per ton, on the average, have been measurably different in successive periods, the cause of such discrepancies should be plainly indicated, as higher labor rate, increased use of explosives, excessive inflow of water, greater proportion of waste, etc., or the reverse.

I am unable to suggest any adequate plan for ensuring the rendering of proper reports by mine managers, except those that depend mainly upon outside coercion. And these, under existing conditions, are of somewhat doubtful efficacy. Legal enactments will accomplish little unless they are of national application. To secure such scope is impracticable now, except by the almost hopeless achievement of equivalent statutes in all the States. The laws of England relating to the auditing of corporate accounts might be followed generally to advantage in this country; but it is not probable that this could be done by the National Government in a constitutional manner. California and New York, perhaps other States, have made a beginning by licensing accountants and thus giving permissive sanction, but without compulsion. Another method is feasible, though it lacks enforcing power beyond what prestige and, finally, custom might attach to it by way of influence. This is the adoption by our Society of a standard scheme, or skeleton administrative report, which would be announced as the basis upon which members of the Society would judge all offerings, and into which scheme, in some ways, all mining enterprises must fit or be considered at least lacking in definiteness.

This plan is not in any sense oppressive. It does not contemplate one whit more than is now exacted from any company which submits to examination of its status by an outside engineer. But it might enable the investor and his engineer to draw some general conclusions as to the investment value of the enterprise. For some years past, I have endeavored by correspondence and personal interviews to arouse the engineering fraternity to action along these lines. It would seem that some practical results ought to accrue from the present discussion. My own conclusion has been that too many have failed to realize how simple the scheme really need be to accomplish the desired ends.

As to the rate of periodicity of reports, varying conditions may possibly dictate diversity of performance. My rule, when clothed with authority, has always been to accumulate detailed records daily from every department, with daily summary reports from heads of departments to the general manager's office (or at least as often as mail service will permit); the board of directors, through the secretary, to receive weekly reports in some detail from the general manager, and monthly or quarterly progress reports to be issued to stockholders by the secretary. Sometimes these last reports are omitted as a regular issue. Monthly financial statements go from man-

ager to directors, with trial balance from general ledger. Usually stockholders receive statements, such as have been suggested, only at the annual meeting, and not in confusion of detail. But particular effort is given to classification of accounts and records in such manner that any director or stockholder can, at any moment, acquire the most accurate information concerning any point he may desire to investigate minutely.

After all, the main-spring of all accounting is system. If this be expertly arranged and rigidly enforced, there will be no difficulty in realizing all the benefits contemplated by this discussion. Without system in daily practice, no reports can be made to adequately epitomize the business of mining or anything else. By properly instituted and operated system the whole history is made self-recording and reports cannot go wrong, without discovery the moment any question is followed back along its proper course through the records. Simple statements similar to those emanating from Alaska-Treadwell are most satisfactory. Anyone familiar with accounts must recognize at a glance that these come not forth by guess or by crude computations from meagre data. They can only be made thus comprehensive and simple, though explicit, by careful attention to the amassing of details as they occur. By system, the mere stoppage of leaks that many mines disregard, yields the substantial dividends paid by the above mentioned and other well managed properties. Guard the wastes and the reports will not need a pattern presented by law or institute. They will become models by virtue of their inherent perspicuity.

F. J. H. Merrill.—(Communication to the Secretary.)—The proceedings of the New York section contain an important discussion of fundamental principles of mining investment, by Mr. H. S. Munroe, and this discussion is made the basis of a forceful resolution recommending that mining companies include in their annual reports certain accurate statements for the guidance of investors. The discussion and the resolution constitute a concise and conservative statement of information to which the investor is entitled in connection with established mines, but for the protection of the vast mass of the public that is daily invited to help forward with its savings the business of mining, a much broader influence must be exerted so as to cover the mining business in the primal stages of its various enterprises. For every investment made in established mines, hundreds are made in the development of prospects, and these investments are for the most part a result of the efforts of those active members of society known as 'promoters'.

The promoter is, essentially, a person who seeks profit by inducing others to invest. In the large majority of cases he knows little and cares less about the merits of the property on which he is selling stock, or which he wishes to capitalize. In a smaller number of instances he hopes, besides realizing a commission from the transfer or capitalization of a property to derive an income from future dividends or a substantial profit from appreciation of stock

values. In a small minority of cases, he is an honest man with a merchantable proposition, striving to interest capital in a legitimate business.

Some means might be devised to separate the sheep from the goats and protect the investor. Practically there stands in the way that weakness of human nature which the late P. T. Barnum recognized and cultivated to his profit—the willingness to be deceived by marvelous tales. Everyone who has lived among mines knows the commercial status of a prospect. The most moderately well informed investor could acquire the general principles of the game of chance known as development. Yet, the human mind is such, that a good prospect, in a proved district, presented to the attention of investors in conservative language, telling only the truth, will sometimes linger and die a commercial death. On the other hand, the shabbiest pretense of mineralization, with scarcely enough ore to load a shot-gun, or just enough highly colored oxide or carbonate on the surface to furnish pigment for painting a dog-kennel, may, with the aid of neatly printed literature telling in glowing terms the story of hastening fortune, be capitalized for millions and its securities floated into the coffers of a complacent and expectant public. Often the cloak of religion is lent to this phase of frenzied finance, and a pulpit failure of a temperance lecturer becomes the mouthpiece of benign fortune offering itself to pious investors.

To my mind it is but a short step, ethically, from the highly cultivated art known as salesmanship, when applied to the distribution of manufactured articles, to the methods used in disposing of the stock of some mining companies. True, the manufactured article usually has some value, while the mining stock often has none, and by promises of impossible income persons are often led to invest their savings in mining stock to a larger extent than they could be in ordinary merchandise. But, the mental attitude of the salesman is often as cold-blooded in the one case as in the other and, so far as he is concerned, there may be no ethical distinction. He simply aims to make an income by inducing people to buy the wares he has to sell.

Various remedies are proposed for this abuse of confidence, one of them being the filing of reports on the character of the properties. We see, however, that it is expensive work, even for the Federal Government, to force corporations to tell all the truth about their business. Besides, unfortunately for the investor, the business of mining is of such a character that the promoter is often able to recite the mistakes of experts to stimulate hope among the ignorant. The history of Cananea is a favorite example. Turned down repeatedly by experts whose imagination could not foresee the possibilities of geological conditions with which they were unfamiliar, in the hands of men who fought for financial existence under the stimulus of hope rather than accurate knowledge, it became a great producer of copper. Under the supervision of paternal influences guarding the investor from speculation in unknown quantities, Cananea would never have been developed. On the other hand, at Tombstone we have seen the new Consoli-

dated Company organized under a maximum of expert advice and with substantial assurance of success, crippled by an unexpected and unprecedented flow of water, the pumping of which for several years has brought great expense upon the promoters of the enterprise and seriously delayed the development of the large orebodies which were expected at and below the 1000-ft. level.

In my judgment, the only safety lies in the education of the public to the point of realizing the elements comprised in the mining risk. Commercial statistics show that of those who engage in business only about 2% succeed. This applies to the business of the corner grocery, cigar stand, and other everyday items of commerce. Probably the mining record is no worse than this. The danger in mining, above other branches of business, is, in credulous and hopeful people being led to believe that unbusinesslike profits are certain and that ordinary business risks have been eliminated. The better way to protect the public is, therefore, to teach it that for one prospect that can be made a mine, many must fail; that a mine may be a success for one or two men, and too small to bear the expense of operation by a company; that a mine may succeed, and yet not pay larger returns than some safer form of investment; and that unusually large returns are, as a rule, only secured by taking large risks.

Another serious feature in mining, as in many other branches of business, is the fact that there are two separate and distinct elements, the quality of the property and the character of the management. A good mine may be unprofitable under careless management, and, on the other hand, a property of very low grade may, under economical and skillful management, be made to pay well. Many a group of investors has, to its sorrow, entrusted its money to a manager of the not uncommon type which takes for its guidance the motto: "A mine that needs careful management is no good."

There is probably no mining district in the world that does not bear traces of the operations of some company which began by rioting in extravagance and spent all its ready money in buildings, machinery, and general improvements before developing any ore. Dishonesty and incompetency in management can be guarded against in mining by methods similar to those employed in other branches of business, although it is inherent to mining that distance of the seat of operations from centres of civilization often exposes a superintendent to temptations and to opportunities for dishonesty that might not occur in a different business. On the other hand, in many cases the bulk of the stockholders' money is spent in city offices and salaries and never reaches the mine manager.

The conclusion to be drawn from all this is that the question of protecting the public from pitfalls in mining by legislation or other supervision is complex, and not simple. Commercial education will be by far a more potent factor.

F. W. Bradley.—While mine reports are generally elaborate as to working costs, and while information of that character is very fully given, they are shy

on details as to the actual ore reserves. Detailed figures as to values and tonnage and the condition of the bottom of the mine are hardly ever found in such reports. I think that the full protection of investors calls for such details. I have in mind annual reports on a certain mining property in Mexico: I have looked through these reports for several years past for a statement of ore reserves in order to get some idea of the life of the mine. While ore reserves are touched upon as a mere incident, there is a vast amount of material to be found in these reports on the cost of the trail and the difficulties of getting stuff over the trail, the telephone line, houses for natives, and the difficulty of securing native labor, fuel, mules, etc. The point I am trying to make is that, for the protection of investors, a mining report should not only state facts as to costs and receipts, but that instead of reciting all the difficulties in connection therewith and elaborating on those difficulties, it would be better to give more detail as to ore reserves. There need be no apology for costs. There are always conditions that affect the costs, and a good manager cannot get away from conditions that are responsible for his costs, unless he has developed sufficient tonnage to justify him in going to the expense of changing such conditions as can be changed by creating better facilities. If there is any elaboration in a mining report it should be on the ore reserves and the developments as effects the future of the property. That is all that occurs to me in reference to the question: "What are the essential items of information which should be contained in mine reports for full protection of investors?"

George W. Starr.—In other words, your idea is that in giving ore reserves you should give the value of those ore reserves: the number of tons of a certain value, and give it in such a way as to indicate the value of the mine, not to give the tonnage alone.

F. W. Bradley.—Yes; my idea is that most mining reports evade what there is actually ahead in tonnage and value; that is the most important item to the stockholder. They elaborate on a great many things not of special interest to the stockholder, even though they are to the manager because they recite his troubles or hopes. The thing of specific interest to the stockholder, and which he should know for his full protection, is the life of the property and its future chances. That information is not to be found in most mining reports today, and in order to evade it, they have to elaborate on something else.

George W. Starr.—Don't you think it would be well in making reports to give the value of the tonnage: in stating ore reserves for certain levels to give the value per ton as well as the number of tons?

F. W. Bradley.—I think a manager should go on record at least once per year and make some kind of a guess as to the values and tonnage ahead of him. The nearer a manager can make his guess or estimate fit with the actual yield, the more valuable he is. Stockholders are entitled to truthful information, not only as to what a mine is doing, but as to what its future chances are, and they should not be deceived by reports that would needlessly elate or depress them.

MINING METHODS IN THE NORTH.—II.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The frozen condition of the placers in Alaska and the Yukon seemed, at first, an insurmountable obstacle. In the end, it proved an aid to mining. To sink a shaft in the creek deposits of a warm climate means a persistent contest with water. Pumps are necessary, or a long and costly drainage adit. The loose ground requires careful timbering. Some of the best portions of the channel may be unworkable because of an excessive influx of water. All of this would have checkmated the diggers of the North in the early days of discovery. Pumps were 1500 to 2000 miles away, heavy timbers were scarcely to be obtained in most localities, a fight with water would have discouraged men unused to mining, as were most of those that rushed to Dawson, Fairbanks, and Nome.

The frost, indeed, was the miner's friend. It enabled him to sink a shaft even in the bed of the creek; it permitted him to dispense with timbering; it allowed him to burrow with safety and to follow the layer of golden gravel with impunity under the ice-bound surface. Moreover, it obviated work on a large scale. One man could, and sometimes did, work alone, descending the shaft, filling the bucket, ascending to the surface, hoisting the load, and so forth. No machinery was needed save the simplest tools; no organization was required, beyond a willing partner; no capital, save muscle.

Even today the prospector avoids the thawed areas. Such exist along certain running streams, and in flats where the moss has been washed away. Evidence of a thaw is afforded by the vegetation, for willows will not grow where the gravel is frozen. In some cases a river valley may be partly thawed, partly frozen. In many instances the work of 'drifting' has to be confined to the sides of a channel, the centre being dangerous on account of caving, due to thawing. Thus Bear creek, a tributary of the Klondike, proved unsuited to drift-mining on account of water, and many rich spots in that valley remain virgin for this reason. Most of the pioneers were so inexperienced that they started work in the centre of the claim, instead of at the lower boundary and working upward, so as to utilize the gradient. Thus No. 38 Below Discovery on Bonanza was worked in the winter of 1897, and at intervals since, being finally sold for \$3500. It was supposed to be exhausted. Yet last July the operations of 6 men per shift, or 12 altogether, merely by shoveling into sluice-boxes from an open-cut, cleared \$1200 in two days.

The method of shoveling into sluice-boxes is suited to shallow rich ground. This form of mining supplements ground-sluicing. The prospector first tests the gravel by washing a sample in a pan. A pan holds about 20 lb. of ordinary gravel. Next he may employ a 'long-tom', essentially an inclined surface over which the gravel is washed. From 6 to 10 ft. of launder or sluice is set at an angle; at the head of it a hopper or box serves to hold from 50 to 150

lb. of material, which is then flushed, a little at a time, down the slope, by the action of water thrown out of a scoop or small bucket fixed to a handle. To arrest the gold, cross-bars or riffles are nailed to the bottom of the launder. In addition, mercury may be employed, or even amalgamated copper plate. In such a case the plate is covered with wire screen or perforated sheet-iron, the effect of which is to size the gravel, causing the larger pebbles to slide down the slope, while the fine stuff sinks through the apertures and comes in contact with the mercury and amalgam. The 'long-tom' was familiar to the early Californian miners, and in its simplest form dates back to the very beginning of the world-wide search for gold. In order to facilitate the saving of gold, a shaking motion was imparted, merely by placing the inclined sluice-box or launder upon rockers. This constituted the 'rocker', which is shorter and more compact than the 'long-tom', the quicker separation of the gold rendering unnecessary a long surface. Much gold has been won by means of these devices. They are still in use.

On the sea-beach at Nome the traveler can observe the simpler forms of gold-saving apparatus. In August, 1908, more than 100 men were employed in washing the 'ruby' sand concentrated by the action of the surf along the foreshore. The sand has a brick-red color by reason of the garnet it contains; this garnet is derived from the prevailing country rock of the region, namely, schist. Through the erosion of the schist the gold also was liberated from quartz veins and concentrated by the waves that in tidal sequence play upon the shelving strand. The arrangement employed to extract this gold is a form of long-tom, consisting of an inclined box or sluice with a false bottom of galvanized iron, or tin-plate from a coal-oil can. This is punctured with holes so as to act as a screen separating the fine stuff from the coarse; the latter runs down the slope into the sea, at the edge of which the apparatus is erected. The fine sand, including the particles of gold, drops through the false-bottom on amalgamating plates. These are of copper, usually silver-plated. At the end of the copper-plate there is, ordinarily, a bit of carpet, matting, or wire netting to serve as a check on any gold or amalgam escaping from above. At the upper end of the box or launder, the sides are raised, or a regular hopper is constructed; into this the sand is discharged from a bucket, emptied from a wheelbarrow, or shoveled direct from the ground that is being exploited. While one operator attends to this part of the work, his partner is furnishing the water to wash the sand down the incline, standing with gum-boots in the tide and swinging a ladle consisting of a bucket fixed to a long wooden handle. Sometimes, for convenience, a temporary dam is made with bags of sand, forming a pool which is renewed by the waves that break over it at intervals. Some of the contrivances that I saw were pathetically crude; in one instance, a small strip of old carpet and a few globules of mercury constituted the gold-saving device. In 1899, the beach-workers got as much as \$5 to \$10 per pan; and even with the roughest contrivances, of the kind just described, some in-

dividuals in one summer season of only four months took \$30,000 to \$40,000 from the diggings on the shore. Today a man can still make \$3 per day on the Nome beach. Two partners told me that they

smash all the machinery built by the men who are digging fortunes from the fringe of Bering Sea.

Sampling with a pan was followed by extraction on a small scale by means of rocker or long-tom.

Such washing was intermittent and did not require much water. If the creek deposit warranted an enlargement of the operation, the next thing was to shovel into a longer sluice-box or series of sluice-boxes, and wash the gravel by means of a more nearly continuous supply of water conducted through a canvas hose. This hose is flexible and easily transported; it is usually 14 in. diam. and made of 12 to 14 oz. duck, sewed with 3 seams. Such a hose will last for one season, of four months, the short life being due not to the effect of the water but of the dirt, which causes the thread to rot. In the accompanying photograph this method of mining is clearly illustrated, although, as usual, the value of the illustration is lessened by the posing of the workmen. The hose can be seen delivering water (say, one sluice-head or 50 miner's inches, equal to 75 cu. ft. per minute) into the sluice-boxes. These are four in number, each one being 12 ft. long and 12 to 14 in. wide. They are set on a grade of 8 in. per 12 ft. As the water courses down the inclined surface, the men shovel the gravel into the current, which separates the light and valueless pebbles from the heavy and valuable gold. The small particles of gold are arrested behind the riffles placed in the last two sluice-boxes. These riffles may be either simply cross-bars nailed to the bottom and retaining a sprinkling of

A Rocker in Service.

made \$60 in 3 days. Another operator and his partner got $3\frac{1}{2}$ ounces of amalgam, yielding a little over an ounce of gold, on the day previous. Storms re-concentrate the sand repeatedly; the appliances required are cheap and easily constructed. It is a poor man's mine.

A more elaborate arrangement to be seen on the Nome beach is an extension of the long-tom, being an inclined series of sluice-boxes. From 6 to 10 of these are stretched end-to-end and lined with coconut matting, on which a screen of woven wire is spread. This is from 4 to 2 mesh and even coarser. Mercury is sprinkled on the matting by means of a bottle stoppered with a cloth. The apparatus is set so that the refuse falls into the sea and is removed by the waves. A gasoline engine pumps the water needed for washing the gold-bearing sand. The intake of the pipe is in the sea, and is provided with a screen so as to keep out the drift-wood. Sometimes the pipe rests on a runner, made of two wheels and a connecting axle, so that it can be withdrawn to safety in case of stormy weather, for tremendous storms occasionally smite this unprotected coast and

mercury, or they may be solid blocks of wood placed along the bottom with small spaces between, so as to make a pavement full of little traps

On the Beach at Nome.

for the gold. As the ground is worked out, the sluice-boxes are shifted so that the shoveling is facilitated. If the deposit is wide, it becomes necessary to erect laterals or radiating sluice-boxes, feeding the

main run-way. These are laid on a steeper grade and are narrower than the trunk line of sluice-boxes.

As an example of this simple form of alluvial mining, I may instance the work done for Frank G. Manley on Thanksgiving creek, in the Hot Springs district. First, the moss is removed by means of mattocks; most of it is piled up and burned; the remainder is washed away in the succeeding operations. The top gravel, which is nearly barren and 6 ft. deep, is then ground-sluiced, that is, it is washed with a nozzle under small pressure into sluice-boxes laid on the bedrock, which is one foot deeper than the 6 ft. of overburden. The bottom gravel, one foot thick, and the bedrock underneath, to the depth of another foot, are worked with pick and shovel. When loosened, this mixture of soft schist and gravel is shoveled into the lateral sluice-boxes. These are 12 in. wide tapering 10 in., they are 10 in. deep and lined with pole riffles. Each riffle consists of three or four spruce poles 6 ft. long, 1 to 2 in. apart, held together at each end by being nailed to a transverse bar. These 'shoveling-in' sluices are not more than 60 ft. long, and discharge into the main line of sluices, 18 in. wide, and lined for a length of 500 ft. with wooden blocks $8\frac{1}{2}$ in. square and 1 in. apart. The gradient is $2\frac{1}{2}\%$, diminishing at the lower end to $1\frac{1}{2}$ ft. per 100. As the gravel is shoveled into the sluice-boxes, the men throw the large pebbles or boulders to one side.

This deposit is from 8 to 35 ft. deep, being shallowest up-stream. It has been worked for a width of 100 to 140 ft. and is profitable for a length of 7000 ft. The bedrock is flat, only slightly more than $2\frac{1}{2}\%$; the result is a difficulty in disposing of the tailing. This is overcome by the use of machinery, namely, a scraper of the bottomless type, made by the Washington Iron Works, Seattle. The movements, to and fro, of the scraper are directed by two reels, one of which hauls it forward while the other pulls it back by means of steel ropes. By the use of two ropes, attached to the rear end of the scraper, it is possible to shift it easily and cover more space. The nominal capacity of this mechanical shovel is $1\frac{3}{4}$ cu. yd., but it actually moves one yard at a time. One engineer attends to the whole operation, the scraper digging into the tailing as it accumulates at the foot of the sluice-boxes. One cord of wood suffices to move 200 yards. At the time of my visit (August 12, 1908) 28 men (14 on each shift) were shoveling into the sluices, and the scraper handled the resulting tailing in 5 hours. A clean-up made on that date from the two feet of material covering 4500 sq. ft. of bedrock, yielded 296 oz. gold, worth \$15.50 per ounce. This included gold that had been in the 6 ft. of overburden. The effect of ground-sluicing is to concentrate, the gold sinking on the deeper stratum as the associated detrital material is washed away. Therefore the yield was \$4588 from 36,000 cu. ft. of alluvium, equivalent to \$3.41 per cubic yard.

A good example of mining on a small scale by an individual is afforded by Pappen's Bench, a patch of rich alluvium on the north side of Pioneer creek, in the district just mentioned. The gold-bearing mate-

rial is 3 ft. thick, feathering to nothing at the lower limit; it is 200 ft. wide and perhaps twice as long; it contains gold at the rate of 35 to 50 cents per square foot. Henry Pappen, the discoverer, removed the top dirt and washed the foot or so of stuff lying on the bedrock. This is a slate. No large boulders exist in the deposit. Sedimentation is apparent. The overburden is a light dirt, such as would be washed down a side hill. The grade is 12 ft. in 100 ft. Pappen made \$21 per day with a rocker, erected 200 to 300 ft. below his 'mine'. He trundled 25 wheelbarrows per day. Being short of water and far above the creek, he built a little reservoir on the hillside, making a brush fence to serve as a dam, behind which he caught the drifting snow. Not getting sufficient, he actually hauled snow on a sled and banked it behind his snow-fence or reservoir. The thaw yielded the water he required. But not for long. A wind-storm arose, having a contrary direction, so violent as to blow away his reservoir!

This example of perseverance is worthy of a 'sour-dough', as the old timers are called. It reminds me of a scheme, credited to Henry Bratnaber, of storing the equivalent of water by erecting snow-fences, such as are built to protect railroads. This idea was ventilated last summer, but it was not deemed practicable. On the other hand, it has been suggested that artificial glaciers would store water, the idea being to lead small streams to form large masses of ice during winter and early spring, so as to keep the water near the head of the watercourse, where it can be diverted in summer into the ditches of the miner.

Thanksgiving creek illustrates many of the fundamental problems of placer mining in the North. Ordinary drifting operations, in the old way, by thawing with wood fires, as already described, were rendered impossible by slabs of ice in the clay that constituted a large part of the overburden. This ice would melt so fast as to extinguish the fire before it could heat the gravel adjoining. Moreover, the deposit was too shallow for 'drifting' except at its lower end. It was a strange locality for a placer mine. Thanksgiving creek is a creek only by courtesy; it is a gently shelving plain, almost a flat, a good deal like a tamarack swamp; in fact, the lower end of the 'creek' is a morass devoid of a gravel bed. In 1903 several shafts were sunk (on No. 2 Above) to a maximum depth of 30 ft. These bottomed in a dense dark-blue mud or 'gumbo'. No gold-bearing gravel was found. A drill-hole put down in July, 1908 (by a No. 3 Keystone traction drilling machine) went through the 'gumbo' and disclosed 8 ft. of clay and gravel lying on a hard slate bedrock. This hole yielded gold at the rate of \$4 per sq. ft. of bedrock, the total depth being 38 ft. Most of the prospectors in this locality were misled by the 'gumbo'. Another trouble was due to the yellowish clay in the overburden, this made it difficult to arrest the gold. Some of the old tailing piles have been re-worked; in one instance two men made \$45 apiece per shift by shoveling into sluice-boxes. Later they themselves re-worked their own tailing and made \$15 per day. This suffices to emphasize the poor gold-saving. Some men take great pains to mine their ground and then

show strange carelessness in extracting the gold.

As an example of operations on a larger scale, I may mention What Cheer bar, another bench-deposit on the hillside above Pioneer creek. This is part of the large property controlled by Frank G. Manley.

the surface so as to tear the moss and pull it out by the roots. This moss is then gathered into heaps and burned. Finally, diagonal furrows are ploughed 10 to 12 ft. apart, water is turned into the furrow so as to deepen it and hasten the thawing of the ground.

Shoveling into Sluice-Boxes. No. 1 Above, Anvil Creek.

Thanksgiving Creek. Tailing Dump in Foreground.

In preparing the ground for mining, the first step is to cut down the thin forest of small spruce, then the stumps (2½ ft. high) are pulled out by horses. It costs from \$250 to \$300 per acre to clear the ground. Next a wing or solid-tooth harrow is dragged over

The whole operation is directed toward exposing the frozen gravel to the action of the sun. When the natural thawing has reached bedrock only 7 ft. below the moss which is 6 to 12 in. thick the deposit is ready to be washed.

MODIFIED PROVISIONS OF MEXICAN MINING LAW.

*The new mining law, modified according to the action of the President and the Cabinet, has been submitted to Congress, and will become effective as submitted. It consists of 150 articles, embodying the present laws and the decrees and regulations that have been in force, with some important changes, mostly with the view of removing conflicts in the legal provisions which have been developed during several years. The advantage of a simplified code for mining is obvious and important, as those who have been concerned in the interpretation of the existing statutes will admit. The regulation as to *per tenencias* remains as now. In Article 3 it is provided that matters relating to mining property become subject to the civil code of the Federal District, except as specifically determined otherwise in the law itself. This is of legal interest. The provisions relating to the restriction of mining rights to Mexican companies is absent from the draft submitted, and, what is also important, the restrictions which required the foreigner to secure executive permission to locate claims in the border States is made to apply only to an 80 kilometre zone on the boundaries. However, the conditions of the suppressed Article 144, disqualifying foreign corporations, is made to apply absolutely to this zone. This is likely to affect operations in some of the important districts of Sonora and Chihuahua. Of course, it does not apply to existing conditions of ownership, and there is always the fairly satisfactory expedient of a Mexican holding company with its stock controlled by a foreign corporation, as is now done in several cases.

The articles bearing on these points are as follows:

Article 134. No title-deed to mining property can be issued to foreigners denouncing claims in a zone 80 kilometres wide along the boundary line with foreign States, unless they previously obtain special permission from the executive of the Union. The same formality is necessary when the denouncement is made conjointly by foreigners and citizens. If the permission be refused, the ground denounced will be declared free.

Article 135. The permission to which the foregoing article refers will be necessary to enable foreigners to acquire by any other method mining properties, or liens thereon, within said 80-kilometre zone.

Article 137. Foreign companies are incapable of denouncing or acquiring by any means mining properties or liens thereon, within the zone mentioned in Article 134.

Article 138. All acquisitions in contravention of Articles 134 to 137 of this law are null and void. Suits for their nullification can be instituted either by a party in interest or by the Federal prosecuting attorney, acting under instructions from the Department of Fomento.

Article 139. When by inheritance or judicial award, in payment of a debt, a foreigner acquires property coming within the scope of Articles 134 and

135, he will be allowed a year to alienate such property, unless before the expiration of that time he shall have secured the permission referred to in the same articles.

Article 140. When a foreign company is the beneficiary of the inheritance or judicial adjudication, it must perforce alienate the property within the period of one year.

The law will come into effect July 1, 1909, except that the provisions as to prospecting permits, which are not recognized in the new law, become effective after the promulgation of the law. It is reported that the authorities have not found the results from these permits satisfactory, and that this is the reason for the action taken. The submission of the law and the generally satisfactory outcome of the matter has already had the good effect of restoring full confidence in the Mexican mining industry on the part of foreign investors, a condition which is made more and more evident each day.

In the withdrawal of Article 144 from the new mining law the regulations for foreign corporations are in force as heretofore. The formalities to which foreign companies desiring to do business in Mexico are subject are as follows: Foreign corporations which desire to become established or to create branches in the Republic shall present and cause to be recorded in the Commercial Registry, in addition to a protocolized copy of their statutes, contracts, and other documents relating to their incorporation, an inventory, or their latest balance-sheet, if they have any, as well as a certificate proving that they have been organized and authorized to do business under the laws of their respective countries, said certificate being issued by the Minister of the Republic accredited to each country, or, if there be no Minister, by the Mexican Consul.

The chief expense connected with this formality is the stamp tax on capital, which is one per mil for the first \$500,000; 0.50 per mil on the second \$500,000; and 0.10 per mil on the capital in excess of \$1,000,000.

The documents usually required are a certified copy of the charter, a certified copy of the by-laws, and the certificate of legal incorporation issued by the Mexican Minister or consul. These documents are placed in the hands of a notary-public, who presents them to one of the civil judges, with an application for authorization to 'protocolize' them. The judge, if he finds the papers in order, and the translations, on the faith of an expert's declaration, seem accurate, hands down an order for the protocolization of the documents, which for that purpose are returned to the notary. The notary makes a summary of the documents and enters it in his 'protocol,' adding the original documents themselves to the appendix. He is bound to pay the stamp tax imposed by law on the operation, and he then makes a transcript of the documents, or their translation, certifying to its exact conformity with the originals. This transcript is presented at the Commercial Registry for inscription and annotation. The 'testimonio' is delivered to the representative of the company in Mexico, to be held by him as evidence of the legal existence of the company in the Republic.

THE COPPER OUTLOOK.

Written for the MINING AND SCIENTIFIC PRESS
By M. E. APPELBAUM.

The history of 'copper metal' during the year 1908 was featureless as compared with previous years, and especially with 1907. The market had its periods of weakness and strength, according to the drift of business, but there was notable steadiness of price in the face of unsatisfactory statistics and reported accumulations of metals on the other side, and when we consider the fact that not until near the close of this year did American consumers operate their works even to the extent of 70 to 80% normal, we must come to the conclusion that statistics do not always enable us correctly to judge the market.

In view of the extremely unfavorable conditions that ruled during the greater part of the year, taking into consideration that the production of 1908 has been a record one, and the consumption the poorest in years, and that in spite of it the metal had not again touched the low level established in October, 1907, the conclusion is inevitable that the reported stocks on hand in this country or in Europe are grossly exaggerated. If, however, large stocks are held, it must be by producers who see such enormous consumption of copper in years to come as to be able to dispose of it with handsome profits without disturbing the market as soon as an advance takes place.

Some authorities claim that we start the year with a stock of one to two hundred million pounds. If that be true, it must certainly be that the copper has been carefully concealed beyond trace, and also that the stock on hand must be electrolytic copper only.

One of the best illustrations as to how little copper is available for immediate delivery is the fact that in November, 1907, when navigation closed, about 15 to 20 million pounds of Lake copper was shipped to Buffalo, which meant a saving to the producers of about $\frac{1}{4}$ cent per pound, the difference between lake-and-rail and all-rail rates. This copper was on the market in December and for a few months after, until it was finally absorbed; by that time, of course, new stocks of Lake copper had accumulated. I can state definitely that this year all the Lake producers did not ship to Buffalo more than about 2,000,000 lb. copper, and some of it had already been sold for delivery at Eastern points during the month of December, so that the actual stock was almost nil.

Now, as to electrolytic copper: The independent selling companies have disposed of their output up to January 1, and therefore the accumulated stock, if any, must be in the hands of the largest selling company. If such were the case, it is difficult to understand why that company should withdraw from the market, as was the case in December, and allow the independents to take whatever orders they might choose. My opinion is, however, that none of the selling companies have any copper to speak of, outside of the material already in process of refining.

There remains the European situation: It has been an acknowledged fact that Europe has always been willing to carry a few hundred million pounds

of copper at about the level of 13 to 14 cents per pound. When copper began to advance several years ago, everyone in the trade suggested that a big advance was impossible because the Europeans were over-stocked. As a matter of fact, however, it proved that the copper was carried in Europe in the hands of strong consumers, who simply accumulate at low prices and consume it by the time the market advances; as the demand grows sharper, they again turn buyers, and the same course of events is likely to take place now.

The reports received from Germany, France, and England are of an encouraging nature and such as to make one believe that the rate of exports established during the greater part of 1908 will be closely followed, if not fully maintained, and when one considers the enormous plans for the electrification of the railroads in the United States and Canada, and the fact that it is reasonable to expect a good business year, it is warrantable to suppose that the stocks of copper, if any, will be used up, and that before many months of good business, sharp advances will take place on account of the inability of the producers to supply the demand.

That the visible supply of copper at the present moment is large can best be answered by the fact that when copper was at 26c., and when everyone was predicting 30c. copper, the visible supplies were the smallest on record. Now, when copper is selling at a low level, and the visible supplies are large, everyone is predicting lower prices. A great deal has been said about the production and consumption in the United States; it is easier to estimate the former than the latter. The total production of copper is about one billion pounds, and the consumption in this country is estimated at between four and six hundred million pounds, and if the large exports are added, I again fail to see where the large accumulation could have taken place in this country.

The metal is in an exceedingly healthy state, especially in this country, where the speculatively inclined dealers, who make large commitments of copper, having during the last two months been disappointed with the rather quiet state of the market, sold out their large purchases made before the election; in fact, some of them have been known to turn on the short side, both in London warrants as well as domestic copper.

It is difficult to understand why, if there are large accumulations of copper in this country and in Europe, one can dispose of reasonably large quantities of copper to American consumers at a concession of only $2\frac{1}{2}$ to 5 points, which has been the case during November and December when some of the dealers tried to realize on their pre-election purchases. Another good feature is that the American consumers have been buying for near-by deliveries, indicating that they are supplying their wants as needed and are not buying copper simply on account of an expected advance. Almost nine-tenths of the American consumers have bought very little copper beyond the first of January, and if business will continue to improve we should, by the middle of 1909, be back to a prosperous condition.

SILVER COATING OF AMALGAMATING PLATES.

By W. A. CALDECOTT.

*While electro-plated copper plates have never come into general use in the Transvaal, and while some of the virtues attributed to them may have little better foundation than the fond fancies of the old-time millman, there is yet no doubt that the percentage recovery by amalgamation in the early stages of starting a new mill with plain copper plates is by no means satisfactory. When more stamps or tube-mills and shaking tables are added to a plant already in operation, a little amalgam can usually be spared from existing plates to 'set' the new plates, but even so, greenish stains and patches for some time offend the amalgamator's eye and defer the day when he can view with satisfaction a uniform silvery surface persisting from one dressing till the next.

The use of silver amalgam for setting purposes has frequently been recommended, and I have experimented upon it in various ways, dating from early but unsatisfactory attempts that involved much labor in filing silver coins into powder. The simple method finally adopted was based upon obtaining a pure silver amalgam of buttery consistency containing the silver in the finest possible state of division. If such an amalgam is applied to plain copper plates after the usual scouring some two or three weeks before the plate is put into service, and the plate frequently dressed with the same amalgam during this period, the silver amalgam is given the opportunity to become thoroughly incorporated with the surface of the plate, with consequent benefit to amalgamation when the stamps or tube-mills are started.

Silver amalgam is now commercially obtainable, but if preferred it can be prepared in the manner described by Louis,[†] as follows:

"A sufficient quantity of silver coin (about $\frac{1}{4}$ oz. per square foot of surface of the tables) is dissolved in dilute nitric acid in a porcelain basin with the aid of a gentle heat. The solution is evaporated to dryness very gently, preferably over a water bath, and then heated till the saline mass commences to fuse, and till all its bluish tinge is turned to grayish black, this change indicating that all the soluble cupric nitrate is decomposed, insoluble cupric oxide being left behind. The salt is then dissolved in a small quantity of water and filtered into a jar or beaker. Pure mercury to the weight of about three times that of the silver used, is poured in, a few drops of nitric acid added, and a few pieces of bright iron floated on the surface of the mercury. The silver will at once commence to precipitate and be absorbed by the mercury forming silver amalgam, the process taking a few days to complete thoroughly. The silver amalgam so produced should be of a pasty consistence."

In carrying out the foregoing method, it will be found that small silver coins dissolve more readily than the larger ones, and that small wire nails pro-

vide the iron required in a convenient form. In the process an iron-mercury couple is formed; this serves to deposit the silver present in solution upon the surface of the mercury, which immediately absorbs it while a corresponding amount of iron is dissolved.

If pure silver can be obtained, the evaporation of its solution in nitric acid, with subsequent heating to remove the copper, may be omitted and the process thus simplified, but if silver coin containing copper is used as a ready though somewhat expensive source of silver, and the copper not removed, the resulting silver-copper amalgam will show a greenish surface film soon after application to the plates, owing to oxidation of the copper present. The molecular state of fineness of the silver in the amalgam permits a much more perfect coalescence between the surface of the copper plate and the amalgam than when coarse particles of metallic silver are present in the latter. To ensure, however, a silver amalgam coating that will not tarnish on exposure to the air, time for absorption must be allowed; for this reason the preparation of the plates some time before use is recommended. After milling has started, the coating of silver amalgam is gradually removed from the plates as gold amalgam is scraped off, but by the time the former is all gone its purpose will have been served and its place taken by an equally efficient and permanent coating of gold amalgam.

The cost of coating copper plates with silver in the manner described is relatively small as compared to the value of the amalgamable gold that otherwise passes away with the tailing in the early stages of crushing, and the allowance of half an ounce of silver per square foot of plate area is certainly liberal, as in my own experience a considerably less proportion than this has sufficed.

Minerals that are deposited in veins of moderate depth associated with igneous rocks, and which are probably altogether primary in such deposits, according to W. H. Emmons, are: arsenopyrite, bismuthinite, calaverite, cobaltite, fluorite, kalgoorlite, molybdenite, muscovite, orthoclase, petzite, rhodonite, stibnite, sylvanite, tellurides, tetradymite, and turquoise. Minerals that are secondary in deposits associated with igneous rocks, but not known to be primary, are alum, amalgam, anglesite, antimony, apophyllite, arsenic, atacamite, azurite, aurichalcite, bismuth, bromyrite, calamite, caledonite, calomel, cerussite, chalcantite, chrysocolla, covellite, cuprite, goslarite, gypsum, hydrozincite, lead, leadhillite, limonite, malachite, manganite, melaconite, mercury, molybdenite, psilomelane, pyrolusite, pyromorphite, smithsonite, stromeyerite, tin, and turgite. Few sulphides are limited to secondary deposits; covellite is probably limited to this group, and most chalcocite is secondary.

In the German Empire there are 60 cities having a population of 50,000 or more. Of these, 44 own and operate gasworks, 38 operate electric light plants, 43 have municipal water works, and 10 have their own street railways.

THE NEVADA METEORITE.

Written for the MINING AND SCIENTIFIC PRESS
By WALTER P. JENNEY.

In the latter part of August of this year (1908) a prospector looking for borax in the Quinn Canyon range, in Nye county, Nevada, discovered and located a mass of metallic iron, which he found lying half-buried in the soil among the foot-hills of the range. Cutting off a few small pieces of the metal with a cold-chisel, he returned to Tonopah, where he sold out all his interest in the find and soon after left the country. The region where the meteorite fell is almost uninhabited save for a few sheep-herders and occasional wandering prospectors. The Quinn Canyon range, marked on some maps as the Grant mountains, bounds Railroad valley on the east and, by wagon-road, is nearly due east 110 miles from Tonopah.

The purchaser placed the matter in my hands with

It was lying partly embedded in the soil of a low hill of volcanic rock (andesite), on the westerly slope of the range. The foot-hills in the vicinity are treeless and support a sparse growth of sage-brush and grass. The gentle slope on which the meteorite lay faced northerly and the contour of the surrounding hills was such that, in falling, its course through the air, if at a low angle, may have been easterly, southerly, or southwesterly. It bears some resemblance in shape to a great turtle, and when found was resting on its flat side, with the domed or pyramidal upper surface projecting above ground. The longest dimensions, as it lay, were easterly and westerly, and the depth to which it was buried in the mantle of soil covering the hill did not exceed 10 to 11 in. The contour of the surface of the ground had resulted from extremely slow erosion; there was no evidence that the meteorite had ever been deeper buried, and subsequently exposed by the wearing away of the hillside. The deeply chan-

The Nevada Meteorite.

instructions to find the meteorite, bring it to Tonopah, and open negotiations with various museums in this country for its sale.

Only a general and imperfect description of the locality had been obtained from the original discoverer and, in consequence, the first attempt to find the meteorite failed; it was not until a second search was made that, with the help of a guide, it was found. These two trips by automobile made by me to find the meteorite covered 430 miles. Later a freight-wagon with six horses and three men, provided with a derrick and chain-pulleys went to Quinn Canyon and hauled the meteorite to Tonopah, the nearest shipping point on a railroad; the round trip consuming eight days. Great care was taken that the polished surface of the meteorite should not suffer abrasion; as soon as loosened from its bed, it was wrapped in sacking and reached the Tonopah Bank, where it is now stored, unimpaired.

The point where the meteorite fell is 90 miles due east of Tonopah, 18 miles north of the Mount Diablo base line, and 100 miles west of the Utah boundary.

neled and pitted upper surface of the meteorite was covered with a thin smooth skin of magnetic oxide, which had protected it from corrosion; even the portion buried was little rusted. The outline, while extremely irregular, is rudely oval, measuring on each diagonal of the ellipse, 44 in.; the breadth is 34 in., and the circumference 132 in. It is 20 in. high and is estimated to weigh 4000 lb. A few small prominences were cut off by the prospector who found it, in order to determine the composition; the amount removed was not more than one or two ounces, so that the meteorite is practically as it fell. Analysis shows that this meteorite contains from 90 to 95% iron alloyed with 5 to 10% nickel. On etching a polished surface, the Widmannstättian figures appear as closely spaced brilliant lines on a dark ground; in places the outer surface of the meteorite displays an octohedral crystalline structure in grouped equilateral triangles. However, the characteristic Widmannstättian pattern can only be obtained when a large surface of the meteorite is etched.

All the evidence gained from an inspection of the

meteorite before it was removed from its bed, seems to support the view that it is a comparatively recent fall, probably within the last 20 years. The wonderful preservation of the surface shows that it has not been long exposed to the weather. The deeply channeled surface, produced by the liquation and combustion of the complex metallic alloy, caused by the intense heat generated in its passage through the Earth's atmosphere, is evidence that the meteor traveled far, before coming to rest where found; that is, its path must have been nearly tangent to the surface of the Earth. This is confirmed by the shallow depth it penetrated the soil; further, it is possible that it ricocheted on the flat side before the momentum with which it was traveling was finally arrested.

This aerolite is supposed to have fallen in 1894. Residents of Candelaria, at that time, recall the passage of an immense meteor that traveled in an easterly direction and was seen to fall far to the east, beyond where Tonopah now stands. Articles appeared in the San Francisco *Examiner* and in other California papers, describing this meteor as entering the Earth's atmosphere over the Pacific Ocean, crossing the Coast range, the Sacramento valley, the Sierra Nevada mountains, passing nearly over Bodie (California) and Belleville and Candelaria (Nevada), to be lost in the desert to the east. Its fall was recorded by the U. S. Weather Bureau at Reno, Nevada. Several residents of Tonopah saw the meteor when it fell. Among them is Fred Corkhill, superintendent of the West End Mining Co. Mr. Corkhill, who at that time was living in Candelaria, states that on February 1, 1894, about 10 o'clock in the evening the residents of Candelaria observed the meteor, which passed directly over that place and was seen to disappear in the east. It gave an intense blinding blue-white light, so dazzling that you could not see the meteor itself. The illumination was so intense that the interior of rooms in the buildings that had shutters closed was lighted up as brilliantly as day. The rush of air after the passage of the meteor lasted a minute or more. After it had passed there was a loud explosion accompanied by a powerful jar. Mr. Corkhill wrote an article on this meteor and it was published in the MINING AND SCIENTIFIC PRESS in the spring of 1894. The place where the meteorite was found is 130 miles due east from Candelaria.

[Here follows the account sent my Mr. Corkhill to the MINING AND SCIENTIFIC PRESS of February 10, 1894.—EDITOR.]

To the Editor: I send a description of the meteor that fell at this place on the night of February 1st. The thermometer registered 15 degrees above zero. At 10 o'clock 7 minutes a brilliant meteor appeared, coming from the southwest. It made a tremendous illumination, suddenly, as if a great flash light was thrown in well-lighted rooms, wherever a corner of window curtain or shade was not tightly drawn. So intense was it in brilliancy that those who were out of doors were dazed, and but few could tell whence it came or whither it went. It was of a dazzling electric blue, like manyare lights had suddenly shot into

existence. The illumination lasted about four seconds, disappearing in the northeast. The illumination brought all who were awake to their doors, awe stricken, thinking some slumbering crater had burst into flame.

Thirty seconds later a terrific explosion occurred, like tons of dynamite suddenly exploded, shaking the hills and echoing through the rocky caverns.

It was like a huge bombshell had been hurled in our midst. There followed a boiling and sizzling roar, like an immense mass of red-hot iron cooling in water. The sound grew fainter and gradually died away. This lasted about fifteen seconds.

Those who were sleeping and did not see the illumination were aroused and rushed out of doors,

Showing Position of Tonopah and Candelaria.

supposing it to be an earthquake or that the crack of doom had come.

When the snow melts and the focus of the explosion is definitely located, a search will be made for the meteorite.

None who saw or heard this meteor will forget it, and they will relate it in future years as a great event; nor will any one here desire to be nearer to those celestial bombs than he was this night. Some ducked their heads to let it go by and considered it a very close shot for a star.

FRED CORKHILL.

Candelaria, Nevada, Feb. 4, 1894.

On Claim 15 Above Discovery (at Lat. 64° 59' North) on Ophir creek, 85 miles from Nome, Alaska, four pans of dirt yielded 70 oz., or \$1250, and one single pan gave 25 oz. of gold.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

CANDLESTICK.—No. 904,732. William Stephens, Ironwood, Michigan.

A device of the character described constructed of an integral sheet of metal and comprising a handle returned upon itself at its rear end and vertically enlarged at its other end to form a cross piece that is extended upwardly and returned upon itself to form a downwardly facing hook, a prong extended forwardly from the cross piece, laterally disposed strips extended from the cross piece above and below the prong and having their ends curved to form split rings constituting a candle socket, a cross bar connecting the extremities of the strips, and a finger piece extended from the cross bar and passing between and beyond the extended strips.

PROCESS OF SMELTING ORES.—No. 891,630. Frederick L. McGahan, St. Louis, Missouri.

The process of smelting ore, which includes heating the ore in contact with a combustible, so as to liberate gases and other volatile products, withdrawing said gases and other products, adding steam to said gases and other products, subjecting the admixture to a temperature high enough to partially dissociate said steam, and returning the resulting aeriform body to the smelting zone of the furnace.

TUNNELING-MACHINE.—No. 900,950. Olin S. Proctor, Denver, Colorado.

In a rotary tunneling machine, the combination of a supporting frame, a tubular shaft revolubly mounted on said frame, a rotary cutter head secured to one end of said tubular shaft, a plurality of operative rock-drilling engines arranged to cut the breast area of a circular tunnel, said cutter head having ports leading from said tubular shaft to said rock-drilling engines, means including a motor for rotating said tubular shaft and cutter head, means for connecting the opposite end of said tubular shaft to a supply of suitable drilling engine actuating fluid, a muck catching cylinder on said supporting frame surrounding said cutter head, and

means for conveying the muck from said cutter head and cylinder to the opposite end of said supporting frame from said cutter head.

ELECTRIC PICK MINING-MACHINE.—No. 903,508. Alfred Sandstrom, Chicago, Illinois.

In combination, a reciprocatory tool, a motor, means operated thereby for producing a pneumatic drive and including a cylinder and piston movable relatively to each other, to the movable one of which parts the tool is connected, and releasable engaging means for the movable part adapted to allow the release and forward drive of the tool when the air pressure overbalances the hold of the engaging means.

ATTACHMENT FOR MINERS' CAPS.—No. 905,682. William Firman, Ottumwa, Iowa.

A lamp holding attachment for miners' caps embodying a supporting plate, a match receptacle disposed upon the rear side of said plate, said receptacle being open at one end and closed at its opposite end and formed with upper and lower longitudinal flanges and an end flange at its closed end, such flanges bearing against the plate, and fingers formed upon the ends of the top and bottom flanges and bent into interlocking engagement with the side edges of the supporting plate.

CONTINUOUS FILTER-PRESS.—No. 905,129. Alexander J. Arbuckle, Johannesburg, Transvaal.

No. 905,129

No. 903,948

In filtering apparatus, the combination of a vessel and a piston reciprocal therein, said piston carrying filtering means, means for removing the separated liquid from the piston and means for obtaining the flow of a portion of the separated liquid through the filter in a direction opposite to that of the filtering flow.

ROCK-DRILLING MACHINE CHUCK.—No. 903,948. Lewis C. Bayles, Johannesburg, Transvaal.

In a rock-drilling machine chuck the combination of the head and U bolt with a half bushing positioned in the bore of the head and non-rotatably retained therein by longitudinal projections engaging corresponding longitudinal grooves, as set forth.

Publications Received.

Any of the books noticed in these columns are for sale by or can be procured from the MINING AND SCIENTIFIC PRESS.

RESERVOIRS FOR IRRIGATION, WATER-POWER AND DOMESTIC WATER-SUPPLY. By James Dix Schuyler. 2d. Ed., revised and enlarged. Large 8vo., pp. 573, Ill., Index. New York. John Wiley & Sons. 1908. Price \$6.

Mr. Schuyler's experience has been so large in arid countries that he presents a particularly full review of the problems of constructing and maintaining dams and reservoirs under the trying conditions so commonly met in the West. The book is not an engineering treatise, but a discussion of actual cases arising in practice, and the means adopted to deal with them. It thus supplies a need felt by every engineer in giving such a bill of particulars as no theoretic consideration of difficulties can properly cover. In this book are collected details of more dams than will be found discussed in any other treatise, and the profuse illustrations elucidate the text. There are 387 cuts and plates, 234 of which the publishers' announcement declares to be new. The utilization of hydraulic methods for making fills is explained in great detail, as also are the methods of rock-fill construction, masonry, earthen embankment, and the more recent adaptation of steel in all-steel dams, and in reinforced concrete. Sedimentation in reservoirs is reviewed, and the effects show that the difficulty is not as serious as had been anticipated, even under such severe circumstances as those existing at the Sweetwater dam in San Diego county, California. The total filling there has been 900 acre-feet since the work was completed in 1888. The solids deposited show an average of 1% for the total water passing through the reservoir, and the fact is adduced that the thickness of the deposit has varied almost directly with the depth of water. An interesting account is given of a mine-dam in the Curry mine at Norway, Michigan, which sustains a pressure of 277 lb. per sq. in., the static head being 640 ft. The work is one of great interest to engineers, and should appeal likewise to intelligent laymen.

HANDBOOK FOR FIELD GEOLOGISTS IN THE UNITED STATES GEOLOGICAL SURVEY. By C. W. Hayes. 8vo., pp. 159, Ill., Index. Washington. Published by the Survey, 1908.

This little pocket volume is something more than a mere list of what to observe, but even as such it is invaluable. It will serve as mnemonics to save the field geologist from omissions in collecting data. Beyond this useful function it undertakes to explain how to collect the notes needed to interpret the salient geologic features in an areal survey. For example, it details the kind and method of observation needed for determining the thickness of inclined strata from the outcrops; how to observe and plot the position of a fault-plane; how to determine the character of volcanic phenomena, whether dike, laccolith, sill, or other form; and how to collect and record proper data concerning rocks. The book will be a great aid toward system and uniformity of method among field geologists. It should be in the hands of every man having to observe and interpret geologic fact in the field.

MINERAL PRODUCTIONS OF CALIFORNIA FOR 1907. Bulletin No. 53 of the California State Mining Bureau. A valuable feature of the pamphlet is the series of county maps, showing all railroads and stage-roads, with distances between stations.

PRELIMINARY REPORT ON THE MINERAL RESOURCES OF OKLAHOMA. By Chas. N. Gould, L. L. Hutchison, and Gaylord Nelson. Bulletin No. 1 of the Oklahoma Geological Survey.

MINE SAMPLING AND CHEMICAL ANALYSIS OF COALS. tested at the U. S. Fuel-Testing Plant, Norfolk, Virginia. By John S. Burrows. Bulletin No. 362, U. S. Geological Survey.

THE MAGNESITE DEPOSITS OF CALIFORNIA. By Frank L. Hess. Bulletin No. 355, U. S. Geological Survey.

Commercial Paragraphs.

The WESTINGHOUSE ELECTRIC & MANUFACTURING Co. has again become the property of the stockholders, after having been in the hands of receivers since October 23, 1907. The petition for the discharge of the receivers was made on December 5, in Pittsburg, before Judge Young of the United States District Court of the Western Circuit of Pennsylvania, and was immediately signed by him. G. B. Gordon made the address to the Court, in which he gave a statement of the company's affairs prior to the receivership, explained the causes which led to the establishment of the receivership, presented a report of the operation of the company during the tenure of the receivership, and finally led up to the great work which has been accomplished within so short a time by Mr. Westinghouse and the various committees in bringing about the rehabilitation and re-organization of the company. He emphasized the fact that during the year the receivers had been in charge they had not only succeeded in paying off the interest on the bonds, as it fell due from time to time, but that they also kept the large factories of the company in operation during the entire time, doing an excellent business at a net profit of over \$1,000,000. The action of 5000 employees subscribing for \$600,000 of stock of the company was another feature presented to the Court. It was also brought out that the company under the re-organization would in every way be in a better condition than at any previous period in its history, as it would start upon the new regime with cash on hand amounting to more than \$15,000,000, with an indebtedness of only about \$200,000.

The DEARBORN DRUG & CHEMICAL WORKS announces that Herbert E. Stone has been made manager of sales in the Eastern department, with headquarters in New York. Mr. Stone was formerly president of the N. A. S. E., and recently manager of the Pittsburg office of the Chapman Valve Company.

The WOOD DRILL WORKS, of Paterson, N. J., has appointed the Harold L. Bond Co., of 140 Pearl street, Boston, Mass., as its exclusive agent for the sale of Wood rock-drills in the New England States. The Harold L. Bond Co. also has offices at 42 Broadway, New York, in charge of Joseph C. Sealy.

The LAIDLAW-DUNN-GORDON Co. has recently closed a contract with the Stewart-Kerbaugh-Shanley Co. for a large compressor-plant to be used in connection with the latter's 14-mile contract on the Catskill Mountain aqueduct to supply water for New York City.

CHALMERS & WILLIAMS advise that they have recently received an order from the Socorro mines, Silver City, New Mexico, for a 30-stamp mill, including a 48 in. by 18 ft. tube-mill and two 48 in. by 25 ft. Burt rapid cyanide filters.

The FRED M. PRESCOTT STEAM PUMP Co., of Milwaukee, Wisconsin, has opened a district office in the City National Bank Bdg., at El Paso, Texas, to cover the growing business of the Southwest and Mexico.

WHITE & NEWCOMB, of Mexico City, have the contract to erect the 12 Brown agitating tanks and 18 solution tanks, all of steel, for the Esperanza Mining Co., at El Oro, Mexico.

The HAMMOND IRON WORKS, Warren, Pa., has opened an office in Mexico City, Mexico, at Cinco de Mayo 32, Francis E. Pratt being in charge.

Catalogues Received.

The FORT WAYNE ELECTRIC WORKS, Fort Wayne, Indiana, has lately issued 'A Practical Guide for Transformer Testing', which should be a great help to those having such testing to do.

The NATIONAL BRAKE & ELECTRIC Co., Milwaukee, Wisconsin, has recently issued a pamphlet discussing 'air-compressors for industrial service'. It is called Publication No. 386.

The WESTINGHOUSE ELECTRIC & MFG. Co. has recently published an attractive booklet descriptive of its Type S distributing transformers.

EDITORIAL.

DUPLICATION of work and needless expenditure of the public money is incurred by lack of co-operation between the departments of the Federal Government. The Land Office and the Geological Survey are both in the Department of the Interior, yet the first sends a geologist to examine a district, in order to delimit mineral-bearing areas, after the Survey has had a corps of men in the same district for two years. Uncle Sam is an extravagant old gentleman.

IN OUR LAST issue we published a letter from Mr. J. R. Finlay expressing disagreement with conclusions appearing recently in these columns. It was a pleasure to publish Mr. Finlay's letter; for careful criticism is more welcome than casual compliment. The views expressed by him will doubtless be shared by many other thoughtful men, and while they are contrary to the opinions we hold, the subject is one well worthy of full discussion. We hope others will contribute, more especially those who disagree with the editorial appearing in our issue of October 17. Mr. Hammond ought to take part and defend his position.

ALASKA owes much to the United States Geological Survey. The geological investigations have been exploratory in character and have been done under great physical difficulties; they constitute today the best source of information both for those resident in the country and for those having a financial interest in the mining operations. Further, the interim reports of progress and development, issued from time to time by Mr. Alfred H. Brooks and his assistants contain much valuable information, the excellence of which is best appreciated by those who know Alaska. We trust that this good work will obtain cordial legislative support at Washington.

HOW MANY people were misled by the advertisement of the Standard Oil Company, through its Assistant Secretary, protesting and warning the public against the imputation that the company or its controllers are interested in smelting, cotton, or other industrial schemes? The public is asked in this advertisement to give no credit "to any statement regarding the Standard Oil Company's views, acts, or intentions unless the same be duly vouched for by an executive official of the Company or by its designated attorneys." What an impudent notice! The records of the courts show that the Standard Oil Company and the predatory persons in control of it have for many years succeeded in killing competition by buying into subsidiary concerns; under various

guises they have tricked their competitors, fooled the public, and suborned railroad officials. No one is to believe that a clever and unscrupulous lot of men is interested in schemes of any kind unless the affidavit of an "executive official" is forthcoming! And yet a number of people will be impressed by this hocus-pocus. Among them our readers should not be found.

ON ANOTHER page we publish the concluding portion of the text recording the discussion held before the Pacific Coast division of the Mining & Metallurgical Society of America in November last. The account as now printed has value as the transcript of a serious conversation between experienced men; it may have the faults of an off-hand debate, but it has the merit of sincerity; and that outweighs all minor blemishes. In a technical society the one unpardonable sin is to "soliloquize under your sombrero" or "talk through your hat"—in plain English: to say, for the sake of effect, what you do not believe. The sequel to the discussion will be published in this journal at an early date. As far as can be judged, the result will be the crystallization of ideas on an important subject.

TECHNICAL men can help themselves and those whom they address by using technical words correctly. It is a strange fact that engineers graduated from universities will speak of "stratas that prospect," of "this data," of a "lense of ore," and of "partially developed ore." Most of our readers will plead 'not guilty' and therefore will not feel hurt by the mention of such lapses. The one last quoted is frequent. We remember a man who announced at the beginning of an article that it was to be a "partial" history of a Mexican mining district; that was not what we wanted; it was the unprejudiced story for which we prayed. 'Partially' and 'partly' perform separate services and signify different ideas; let us add to the significance of language by using the right word in the right place.

ONE of our local vehicles of misinformation, usually styled a morning newspaper, recently published a sensational account of "hot shot falling from the clouds." In a despatch imputed to the Associated Press, the reader was informed that "molten rain falls on the housetops of the peaceful town of Santa Cruz." A woman named Mrs. Burns is stated to have seen "little white threads of smoke rising from the roof where these little red-hot metal globules struck the damp boards. . . . This molten rain continued from about 2 o'clock to 4 o'clock in the afternoon." As a scientific explanation, it is suggested that "this molten precipitation is due to the condensed fumes from the Mt. Etna eruption." There is more of this childish twaddle, but what has been quoted suffices to illustrate the enlightened character of journalism in San Francisco.

FEDERAL aid to State mining schools has been frequently urged, and was recently recommended by formal resolution of the American Mining Congress at Pittsburg. Weakness in educational

facilities is a sad characteristic of many struggling institutions established under the impetus of the Land Grant Act some years ago. The United States has followed this by extending material aid and dignity to the agricultural colleges, which were also beneficiaries by the Act, through affiliation with the work of the Agricultural Department by the creation of Experiment Stations. Under the proposed new Mining Bureau something of like character may arise in connection with the mining schools as a convenient way of enlarging the technological activity which the Bureau is expected to absorb from the Geological Survey.

State Mining Legislation.

At the last session of the California Legislature a bill was introduced in the Senate, known as Senate Bill No. 55, which had for its purpose the supplementing of the Federal mining laws, providing for the manner of locating and recording mining claims. After amendment in committee and elimination of certain objectionable features, to which we invited attention in our issue of February 2, 1907, the bill passed both houses and reached the Governor in the closing days of the session. It failed of approval by reason of the pressing nature of other matters requiring his attention. This bill, substantially in the form in which it passed the last legislature, has been reintroduced at the present session by Senator Henry M. Willis, and is known as Senate Bill No. 32. As we have frequently had occasion to point out in the columns of this journal, California is the only State in the Union possessing public mineral-bearing land that has not a code of laws governing the subjects embraced in the pending Willis bill. There is no law in this State providing for the manner of locating or recording mining claims. While the locators as a rule, through custom and habit, take the steps in perfecting locations provided for in the bill, there is no statutory sanction for them, and recorded notices have but little value as evidence before the courts.

The Willis measure is little more than an effort to express in statutory form the practice common, in the mining regions of the West. There are no radical changes in the customary law, and the lines of the proposed legislation have their counterparts in every mining State in the West where public lands exist.

Briefly, the subjects dealt with are: (1) The contents of the posted notice, the requirements being extremely simple. (2) The marking of the boundaries without specifying the kind of stakes or monuments, in which respect the bill is simply a re-statement of the Federal law. (3) The recording of a copy of the posted notice with the County Recorder within thirty days after its posting, and making recorded notices or certified copies evidence in all proceedings. (4) The manner of making placer locations on both surveyed and unsurveyed public lands. (5) The method of locating, marking, and recording tunnel and mill-sites. (6) The amendment of faulty or defective locations. (7) The privilege of having

location boundaries surveyed by Deputy Mineral Surveyors and making such survey *prima facie* evidence. (8) Providing for proving by affidavit the performance of annual work. (9) Procedure by a co-owner who performs the work, to secure contribution from his associates, and prescribing the method by which the interest of the delinquent co-owners may be forfeited.

Most, if not all, of these provisions have been in successful operation in other States, they have received the sanction and approval of the highest State and Federal courts and the Land Department, they form a simple and safe guide to the miner, and give to his location notice, when once recorded, the value of a paper title, upon which all subsequent proceedings, either for patent or transfer, may be predicated.

There are two provisions of the bill, however, that require modification. Section 1426C of the bill provides: "The location of a placer claim shall be made in the following manner: By posting thereon, upon a tree, rock in place, stone, post, or monument, a notice of locators, date of location, number of feet or acreage claimed, such a description of the claim by reference to some natural object or permanent monument as will identify the claim located, and by marking the boundaries so that they may be readily traced; *provided*, that where the United States survey has been extended over the land embraced in the location, the claim may be taken by legal subdivisions and no other reference than those of said survey shall be required." There is an ambiguity in this section. The Supreme Court of California has held that when surveyed lands are located under the placer laws, there is no necessity for marking the boundaries, and this is the rule followed by the Land Department. This section as it stands leaves room for doubt as to whether such a claim should be monumented or staked. The reference to the sub-division of the public surveys is stated to be sufficient as a matter of description in the notice without other reference. But nothing is said concerning the necessity for marking the boundaries. An amendment to this section is suggested, in order to remove the ambiguity, by adding the following: "and the boundaries of a claim so located and described need not be staked or monumented. The description by legal subdivisions shall be deemed the equivalent of marking."

Section 1426r. is as follows: "The provisions of this act shall not in any manner be construed as affecting any mining district in the State of California, or as requiring a compliance with the provisions of this Act as to the location of mining claims within such district, where such district comprises one county, and the recorder of such district is the recorder of such county."

There is a strong suggestion of unconstitutionality in this section. It has been intimated that it violates the provision of the Constitution that all laws of a general nature shall have a uniform operation. There are possibly two counties in the State, Tuolumne and Nevada, which for a great many years have constituted separate mining districts. As such districts, they have rules and regulations providing for record-

ing and other details of location, not, however, as we understand it, in serious conflict with the provisions of the Willis bill. By the act of the Legislature of 1897, all mining districts in the State were abolished. While this Act was repealed, such repeal did not revive these district organizations. Be that as it may, this method of placing two counties in a class by themselves and exempting them from the operation of a law which is of a general nature is not such a 'classification' as will overcome the objection of non-uniformity. It is possible that the unconstitutional features of this section might not destroy the entire bill, yet it is unwise to retain this feature, as it may afford ground for attacking the entire measure. With this provision eliminated, and there is no substantial reason why it should not be, the measure is wholesome, is distinctly in the interests of the mining industry, and should be passed.

Panama Canal.

Congress recently appointed a special committee of its members to visit Panama, with some hint at duties of inquiry, investigation, or the like. These gentlemen, in obedience to a psychologic law, will henceforward take keener interest in all that relates to Isthmian affairs. So much of good conceivably may arise from junketing expeditions: they inoculate the travelers with the virus of receptivity for information, and stir conceit to display superior wisdom. Whether or not they discovered the financial distress in which the Panamanians are languishing, they will be better able to appreciate and interpret to this country the formal protest by representative business men and bankers against the indiscriminate sale of supplies from the Canal Commission's stores, a practice which has nearly destroyed the commerce of the toy Republic. Uncle Sam has played so carelessly with the toy that he has seriously damaged its condition. What President Roosevelt will do with the protest remains to be seen. It deserves public answer, for back of it lies something more than a clamor for better opportunity to make money; the machinery of Government is said to be not satisfactory, and the restrictions upon free commercial intercourse with Colombia are detrimental to Panama in high degree. Whether this be the conviction of a majority is of course open to question, but the rumblings indicate a large party favorable to re-absorption into Colombia, the mother country. A treaty of amity and commerce has just been negotiated between the United States and Colombia, in which the independence of Panama is recognized. After this graceful act of a wronged nation, it would be a salve to our own honor and self-respect to authorize a plebiscite in the little Republic to determine whether it should retain autonomy, or return to the old allegiance. Our interests in the Canal Zone will rest as securely under treaty with Colombia as with Panama. We would not then be stultified by equivocal and farcical arrangements that give the lie to those principles on which our institutions were established. Now is the time for us to remove the blot from our escutcheon.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. C. HOOVER is here.

SEELEY W. MUDD is at St. Louis.

HARRY H. WEBB has gone to Carlsbad.

A. C. BEATTY has returned to New York.

CURTIS H. LINDLEY is at Globe, Arizona.

SPENCER PENROSE and CHARLES M. MCNEILL are at Salt Lake.

ALLEN H. ROGERS is examining the Braden copper mine, in Chile.

H. FOSTER BAIN attended the meeting of State Geologists at Baltimore.

C. W. LININGER is superintendent of the Amparo mine, in Jalisco, Mexico.

Obituary.

FRANK TAYLOR died in London on December 27, 1908. Since the retirement of his brother, John Taylor, a few years ago, he was head of the firm of John Taylor & Sons. He did not have much to do with mining operations, but gave his special attention to the business of the Sandycroft foundry, near Chester, which is owned by the firm.

ALMARIN B. PAUL died in San Francisco on January 12. He was born at Bridgton, New Jersey, and was 85 years of age. A pioneer of mining in California, he made a specialty of the saving of fine gold. He built the first mill in the Grass Valley district and was an active mine operator on the Comstock. His last operations were in Shasta county. As a contributor to this journal, as a practical millman, and as a participant in all the early developments in California, he was a notable figure, and his passing is widely regretted.

General Mining News.

ALASKA.

B. A. Chilberg and John Brower have purchased the King Solomon, Queen of Sheba, and Happy August claims on Newton gulch previously owned by August Homberger and Mike Young. The properties are those over which there was so much excitement during the past summer. They contain that wonderful decomposed ore which assayed so high and which gives such promise of being one of the greatest mines in Alaska. The consideration for the sale of the claims was \$200,000. The most important part of the deal, and the one which means much to Nome and this district, is the fact that the new owners of the property are now arranging for the establishment of a large mill on the ground and the installation of 20 stamps. All of it will be completed and in working order by the first day of next August.—A discovery of pay-gravel 500 ft. north of the third beach line at Nome, by Holt, Loveway & Ryan, is said to make the existence of a fourth beach practically certain. The streak is 8 ft. deep and pans run from three cents to three dollars.

ARIZONA.

GRAHAM COUNTY.

The Shannon Copper Co., which recently secured the Weaver mining claims, in the Greenlee district above Clifton, has established a camp and is now working a good force of men on the property. Several years ago Mr. Weaver struck good ore on the property, but the grade was not high enough to work on a small scale. Several mining engineers have reported on the property and the company is doing its work upon first-class advice. The entering of the Shannon into that part of the district means a great deal for individuals owning property in that neighborhood, and if development work on the Weaver claims proves successful, there will be considerable activity in the upper country.—The cable for the New England & Clifton aerial tram arrived last week and was immediately transferred to the mines. Construction work on the tram is progressing rapidly and it will not be many weeks until it will be in running order.

MARICOPA COUNTY.

The news of a sensational gold strike on Kirkland creek has been going about the last few days. It is reported that a vein of exceedingly rich ore has been discovered near the Rudy ranch in Kirkland valley and that a number of claims have been staked off.—It is reported that R. C. Vincent, president of the Duluth-Arizona Mining Co., will soon arrive at the company's property at Black Rock and start work on that promising group. A compressor, pump, and drills will be installed.

MOHAVE COUNTY.

The work of sinking below the 200-ft. level of the Ellen Jane mine, on Music Mtn., is to be started soon. The property is owned by the Nevada-Arizona Mines Co., of which T. J. Grant is superintendent.—All equipment has been placed on the Holy Moses mine by L. Hoffman and the work of timbering up the shaft is under way. Sinking will be commenced in a few days.—Frank Hare, W. P. Eshom, and J. W. Cornelius have made a big strike on a mining claim in the neighborhood of Potts Mtn., near the old McCracken. The vein is 15 ft. wide, with a solid body of ore 8 ft. wide running through it. This ore runs high in copper, gold, and silver. Pannings from the shaft run from \$50 to \$100 per ton in gold.—The Stockton Hill Mining Co. is arranging its affairs for the early resumption of work on the Cupel mine, at Stockton hill. It is probable that the shaft will be sunk several hundred feet deeper and the contiguous veins thoroughly explored.—The Altata mine is to be taken over by a new corporation, recently formed in Chicago. Mrs. Anna Tofte, one of the principal owners in the mines, is in Chicago, conferring

with the other corporators in the perfecting of arrangements for the early resumption of work on the mines.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Bernhardt group of claims on Green Lake Mtn. was the scene of a rich strike a few days ago. In putting down a shaft to a depth of 15 ft. an 8-in. streak of galena ore was cut that carries 72% lead and 15 oz. silver per ton. A contract has just been awarded for the driving of an adit for 250 ft. to cut under the shaft workings at an increased depth of 250 ft. This property is operated by a pool of Georgetown business men, headed by H. W. Kirby.—The Sigafos boring machine just installed at the Georgetown adit on Columbian Mtn. was put into commission today. The machine seems to be breaking the rock at a good rate of speed, but until the tests have been continued for several days the complete results will not be known. A number of directors of the American Rotary Tunnel Machine Co. arrived in camp yesterday and all announce themselves as being more than satisfied over the results so far accomplished. Two weeks are to be allowed in which to demonstrate the worth of the machine, and if the work can be performed as claimed by the in-

Western Colorado.

ventor, a contract will be entered into with the Georgetown M. P. & T. T. Co. for the breaking of 16,000 ft. of ground. A great many operators from various parts of the State are now on the ground witnessing the tests.—H. J. Vancil, of Joplin, Missouri, president of the Joplin T. & M. Co., arrived in camp this week and is now making arrangements for starting work on the 150-ton chlorination plant which is to be built on Clear creek near the portal of the Joplin adit. Plans are being drawn and within from 30 to 40 days actual work will be under way. The mill is to be fed upon ores from the Gambetta vein, where immense bodies of lead-zinc ore are exposed, while contracts will be made for the treatment of a good tonnage of ore from the various mines lying in close proximity. B. J. O'Connell is manager.—Within a short time development is to be started upon the holdings of the East Argentine M. M. P. & T. Co., in East Argentine. For the present the Sidney adit will be driven forward with hand-drills, but as soon as sufficient water is flowing the compressor plant will be used. The Sidney adit is now in Pendleton Mtn. 2300 ft., and from surveys the White, or Mother Lode of that section will be reached within from 125 to 150 ft. Lessees at work on the Ontario vein, cut 2125 ft. from the entrance of the adit, are sending out heavy shipments of smelting ore, worth from \$55 to \$70 per ton in silver and lead. M. Sidney is manager.—The Toledo M. & M. Co. is pushing development work. The adit has now

passed the 400-ft. point and from surveys just made the Toledo vein will be reached within from 40 to 50 ft. The management purposes driving upon a vein recently passed, as a streak of galena is exposed that is from 6 to 12 in. wide, which is said to assay more than \$60 per ton in silver and lead. G. S. Redd, of Denver, is manager. This company intends to install a plant of machinery in the early spring.—Clapper & Co. has taken a lease upon a big block of ground in the Scepter adit, and the property is now being placed in position to permit of stoping. At the point where operations are being centred, a body of lead-zinc ore is exposed for 150 ft. that is 8 to 20 in. wide, while occasional streaks of smelting ore are found that carry as high as 406 oz. silver per ton. The lead-zinc is to be brought to Georgetown for separation at the custom mills.—The Astor-Stewart M. & M. Co. has started work in the re-timbering, enlarging and reducing the grade of the Scepter adit. It is expected to have this undertaking completed within from 30 to 40 days. H. G. Houseman, of Denver, general manager, has been in the East for the last three weeks and advises that large funds have been pledged for the carrying of all plants to a successful issue.—The new 25-ton mill at the Black Eagle mine, situated up Chicago creek, will be started some time during the next two weeks. This is the first plant of its kind ever constructed in either Clear Creek or Gilpin counties, being equipped for chemical-electric extraction. The compressor just put in near the collar of the shaft is running night and day and a heavy tonnage of ore is being mined. The fourth and sixth levels are being driven eastward with the aid of machine drills, and as the ground is opened the showing continues to improve. The orebody on the sixth level is 8 ft. wide in places, and is worth from \$5 to \$22 per ton in gold. It is the intention of J. F. Puchert, who is manager, to shortly start work in deepening the shaft another 100 ft. The Black Eagle is developing into one of the heaviest producers of the Chicago creek district and effort is to be made during the present year for a record-breaking production.—The St. Paul M. & M. Co., controlling a big group of claims on Green lake and Payne's Mtn., is carrying on work in the last named region. The adit is being driven ahead and it is expected that another vein will be reached within the next few feet. Driving is to be started upon a vein recently passed, as a streak of galena is exposed that is from 4 to 6 in. wide. It is understood that this company will shortly resume work in the advance of the St. Paul adit on Green Lake Mtn. The bore is in 1400 ft., and by continuing it for 500 ft. farther the St. Paul vein will be intersected. R. H. Blackman is resident manager.

Georgetown, January 9.

LAKE COUNTY.

Work on the Tenderfoot shaft is progressing steadily, and the lessees hope to have it completed to the desired distance by the early part of the new year. It is now down 120 ft., which is 50 ft. short of the point to which it will be driven.—The Fanny Rawlings has opened a new vein of lead ore that promises to make good with further development. This discovery is in a virgin portion of the property, in which extensive explorations are now being carried on. In addition to this work the Fanny Rawlings is maintaining a steady output from the old workings, in which excellent gold ore was found in the year past.—Thomas Gilroy, who has secured a long lease on the White Prince and Across the Ocean properties on Breece hill, is working three men. He is now sinking a new shaft, and is expecting to get ore in the near future, as the well known orebodies of the Penn and Nettie Morgan mines run through the ground.—During the month of December the Yak tunnel broke all previous records for distance in the same length of time, cutting 358 ft.—about 11½ ft. per day. The breast is now in the Resurrection property, and will soon be in a position to tap the old veins that have already produced thousands of tons of good ore. During the present months the drills will be put to work to tap the old Resurrection shaft, which is now partly filled with water. This

will be a task requiring much care and accurate calculation, as it is proposed to allow the water to flow out gradually, so as not to flood the tunnel. After the old shaft is drained, development work along the property held by the Resurrection can be carried out.

OURAY COUNTY.

A deal has just been consummated whereby the Camp Bird, Ltd., secures a one-year option on eight valuable mining claims on and near the Ouray-San Miguel county line, the purchase price for the property being named at \$10,000.

TELLER COUNTY.

The Portland Gold Mining Co. has declared a dividend of 4c. per share, involving the distribution of \$120,000.—The Jerry Johnson mine, on Iron Clad hill near Cripple Creek, has been leased to Edward Gaylord and associates, of Denver. A hoist is to be installed and power for the air-drills will be obtained from the Western Investment Co.'s John A. Logan plant, on Bull hill. Operations will shortly be resumed at the W. P. H. mill, of which milling plant Mr. Gaylord is manager, and the low-grade ores from the Jerry Johnson mine will be treated therein. The higher grades of milling and smelting ores will be consigned to the valley plants as heretofore.—An amicable settlement of the matters at issue between the Acacia Gold Mining Co. and the Findley Consolidated Mining Co. has been arrived at without recourse to litigation. By the agreement duly filed for record with the county clerk and recorder last week, the Acacia company is allowed exclusive and perpetual right to dump waste rock on a certain portion of the Shurtloff and Pauper lode mine claims of the Findley company, the Findley company to have the right to remove and dispose of said dump as their own property. It is further agreed that the Acacia company shall protect the two shafts on the north end of the Shurtloff claim from filling up and damage from said dumping of waste rock. By the terms of the settlement the South Burns Leasing Co., operating the South Burns mine, will, or has already received a satisfactory cash payment, representing the net value of the ore extracted from within the lines of the Burns claim by the Findley company.—As a protective measure against fire a high-power fire-pump has been recently installed at the surface at the Henry Adney mine on Beacon hill, and similar pumps have been contracted for by other mining companies and lessees. The machinery at the Henry Adney is also being overhauled and it is understood that work on an extensive scale will be shortly resumed.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—With several strikes of importance and the declaration of dividends by the Bunker Hill & Sullivan and the Snowstorm mining companies the new year has opened most prosperously in the Coeur d'Alene.—After an idle period of almost a year, work is about to be resumed on the property of the Rhode Island Co., in the Osburn district. The property has been extensively developed and six feet of excellent ore opened up. It is the intention to sink a winze and if the results are up to expectations shipments will commence.—At the annual meeting of stockholders of the Hector Mining Co., held in Wallace about the beginning of the week, officers and directors were chosen for the ensuing year. John H. Nordquist is president. The report of progress is considered entirely satisfactory, contracts for 250 ft. of work having just been let.—A strike has been made on the property of the H. E. & M. Mining Co., consisting of two feet of clean shipping galena carrying 80% lead and over 20 oz. silver per ton. In addition to the shipping there have been several feet of good concentrating ore opened up. The property is in the Revenue Gulch district and a considerable amount of excitement has been caused by the developments.—After 18 years of steady labor J. Ward, an old-time miner of this district, has opened up an 11-ft. vein of free milling ore in the Ward's Peak district. The strike was made the beginning of the week and samples of the ore

which have been brought down to Wallace have given returns of \$220 in gold. The ore was found at the end of a 900-ft. adit and at an approximate depth of 700 ft.—The Copper King mine and concentrator in the Thompson Falls district has changed hands and after an idleness of several years it is expected that both mine and mill will be started at full blast in the spring. The property, which was formerly owned by Fred M. Steele, of Chicago, has now passed into the hands of the Thompson Falls Copper & Milling Co., the consideration being \$100,000. The new company is financed by Eastern men, but S. A. Hurlburt, of Thompson Falls, has been retained as general manager. The property is an old-time producer and has shipped much rich ore. It is believed that the machinery can be put in order at very little expense.—At the annual meeting of the Swastika Copper Mining Co., held last week, Thomas M. Marlowe, of Missoula, was re-elected president and treasurer; George E. Marlowe, of Wallace, secretary, and J. W. McDonald, of Superior, Montana, vice president and manager. A contract for 300 ft. of work was given to Thomas M. and George E. Marlowe. This will be done in driving a lower adit to intersect the main vein. It was decided to make no further shipments of ore until the completion of the Chicago, Milwaukee & St. Paul railroad some time in the spring. One car was shipped during the past winter and netted about \$49 per ton, but the expenses of hauling were considered too high. An attempt will be made to get sufficient funds to erect a concentrator in the spring. It is the intention of the company to increase the capitalization from \$150,000 to \$7,500,000 in the near future.—The Pittsburg Lead Mining Co., which has been idle for the past three months, will resume work this week with a force of 20 men. The men will be used in driving on the 200-ft. level and in sinking the shaft another 200 ft. Work at the property will be superintended by Sidney L. Shonts, of Wallace, under the direction of Stanly A. Easton, manager of the Bunker Hill & Sullivan.—An option on the stock of the Belmont Mining Co. has been given to a syndicate of Spokane capitalists. An inspection is to be made and, if present plans mature, work will be started at once.

Wallace, January 9.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—The development of greatest importance to the Galena camp is the opening of a 500-acre tract by the Clermont Mining Co., south of Galena. A large amount of prospecting has been done. The twentieth drill-hole has been completed showing ore from 134 ft. to 180 ft. The cuttings run from 9 to 10% zinc-blende with no galena showing. Prospecting was begun 16 months ago and has been kept up all through the panic. Several drill-holes penetrated a limestone bar and below this entered a rich deposit which continued to 300 ft. The ground is being leased, but the company will keep a 10-acre tract upon which the last strike was made for its own development. Shafts have already been started upon sub-leases and ore has been struck at 50 ft. in one shaft.—A rich strike of zinc-blende was made by Page & Co. west of the Wyandotte land. The ore was reached at 100 ft. and a 12-ft. face has been opened. It was upon these tracts that the royalty was reduced last summer with favorable results as an increased demand for leases was made and several strikes have been reported.—The largest and most important sale of ore in the Galena camp for the past year was recently made by Lynch & Williams. It consisted of 1000 tons of ore sold to the Cockerill Zinc Co.—A ventilating drift is being run in the Hartford mine to connect two shafts 325 ft. apart. The large new mill is being run only part of the time, as enough ore is not being produced. The new drift will furnish considerable ore and enable the plant to run longer. This is one of the largest mills in the Galena camp. The ore here is found at 170 ft. and is especially high grade.—In the Baxter Springs camp the Hannibal & St. Joe mine is being re-opened by George E. Ladd. A large pump has been installed.—The Joanna mine has

been procured by Starchman & Caulkins, who have begun operations. Extensive improvements are under way.—At the Chicago-Quapaw mine a deep well is being sunk, which is now down 615 ft. It is to be used to supply artesian water for the mill. During the drilling a large deposit of ore was penetrated from 62 to 85 feet.

Galena, January 9.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—Among the plants recently re-opened is the Church Mitchell mine in the Duenweg district. This is one of the largest plants in that district and has been shut down for seven months on account of low ore prices. A full force of men was put to work last week at advanced wages. The property is operating upon sheet ground.—The Hayseed mine in the Carthage camp is again producing after lowering the shaft to 155 ft. The company is cleaning from 7 to 10 tons of ore per day. The drifts are being further opened up. This property has been under development for several years.—The Plymouth Rock mine in the Sarcovie camp has been taken over by a new company and has been started again after a long idleness. The new owners have overhauled the plant and made thorough preparations for steady production. Both day and night shifts will be run.—The Highland plant, owned by the United Zinc Co., will be re-built. This plant was destroyed by fire some weeks ago. The building was a completed loss, but the machinery was slightly damaged.—The San Gabriel mill, which was moved from the Matthes Bros. tract in Duenweg to the same company's land in the Joplin camp, is now almost completed. The mill is now on the old John Jackson land, owned by Matthes Bros., and thoroughly developed by them during the past year. A shaft has been sunk and a good body of milling ore opened up. The plant has a capacity of 400 tons. It will mean a considerable addition to that portion of the Joplin camp.—W. E. Johnson has just completed a new tailing mill of 200 tons capacity on his land southwest of Joplin. It will treat the piles of tailing upon the land. A large amount of ore can be cleaned, as the mills for the most part were small and not equipped with sludge tables and the fine could not be saved. From 2 to 5% ore can be found in the tailing piles. Little lead is found, the ore being mainly zinc upon this land.—The Lucky May mill in the southwest part of the city has become a steady producer. The 200-ton plant is comparatively new. Since its completion a large amount of development has been done. The prospect was operated by hand-jigs before the mill was built. The deposit is found at 150 ft.—A new tailing mill of 200 tons per shift has been erected on the Cameron lease southwest of Joplin. Both tailing and sludge will be handled. The tailing of the Cameron mill will first be handled and later other tailing piles will be procured. The tailing of the Cameron mine runs from 2 to 5% zinc. The slime tables in the new mill are special devices for saving the very fine ore, usually lost on the ordinary concentrating table.—The best recent lead strike in the camp was made at Spring City in the U. G. Wilson shaft, which has been sunk 300 ft. from the old Argosy shaft. The ore is found at 130 ft. and the shaft and drifts are covered with the ore in a layer formation. The ground is not opened sufficiently to keep the mill running all the time. Development work is being hastened.—The Yellow Dog, the largest plant in the district, has been closed down some time. However, underground work has been carried on in the meantime and rich ore was struck in a stope at 200 ft. The ore was galena of a very high grade. It has not been ascertained whether the ore is merely a pocket or a large deposit. During the shut-down, the Yellow Dog mill has been thoroughly overhauled and rumors are afloat that it is to re-open soon.—Drilling on the Kelley land near the Frisco depot in Webb City has resulted in good strikes of sheet ore at the usual sheet-ore depth. The cuttings assay as high as 8 to 9% zinc-blende.—A shallow strike of ore has been made in the Oronogo camp by the Oronogo Circle No. 2. The ore was found at 80 ft., while the usual run of

ore occurs here at 150 to 200 ft. The 150-ton mill has only recently been overhauled. The plant will soon be operated with two shifts. A new revolving screen has been installed at this plant which has proved efficient in saving the fine. —A large centrifugal pump has been at work in the drifts of the Cock Robin mine in Chitwood and has drained the ground completely. The ground was worked several years ago and was a good producer, but has been filled so long with water that the sides of the drifts are mud covered and the extent of the ore cannot be determined. Development work will now be done.—The new mill on the Norment lease is completed and ready for operation. The plant is a 100-ton structure. The only drawback is the lack of water for running the mill. This is to be supplied from the old shaft and drifts of the Ready Money mine adjoining. A pump has been installed for this purpose.

Joplin, January 9.

NEVADA.

HUMBOLDT COUNTY.

The Cleghorn-Duke lease on the estate of the Seven Troughs Signal Peak Mining Co. is to be equipped with a full outfit of machinery and an extensive campaign of

The Advantages of Rapid Transportation.

development is to be started. The equipment has arrived in Lovelock and is now being hauled out to the property. A 1400-ft. adit is to be started. John Cleghorn is general manager.—Good headway is being made in the sinking from the 200-ft. point to a depth of 400 ft. of the shaft on the property of the Monnette M. & M. Co., which lies just north of the estate of the Seven Troughs Mining Co. Sinking was resumed about a month ago and the shaft is now down to the 290-ft. point. It is expected that the 400-ft. point will be gained within the next 60 days, when a cross-cut will be started to the west to strike the two big veins which have been opened up west of the shaft on the 200-ft. level.—The foundations for the Samuel Hains custom mill have been completed and the erection of the building started. Several carloads of machinery have arrived at Lovelock. C. S. Floyd, of Mazuma, is looking after the construction work.—Julius Lesher, of Oakland, will, it is reported, build a \$14,000 hotel at Mazuma.—Stoping was begun last week on the rich shoot of ore that has been opened up in the north drift on the 200-ft. level in the famous Harris lease of the Seven Troughs Florence Mining & Leasing Co., on the property of the Seven Troughs Mining Co., preparatory to a test run of ore at the Kindergarten mill of the Seven Troughs Coalition Mining Company.

LINCOLN COUNTY.

The Copper King property, nine miles north of Searchlight, owned by Peck & Pauff, will be equipped with new machinery and extensive development started. There is already a shaft down 65 ft. and an adit 50 ft. long.—A new company, called the Lenape Gold & Copper Mining Co., has been incorporated under the laws of Delaware to work the Copperopolis group, directly south of the Philadelphia-Searchlight. J. Frank Allee, of Delaware, is president, and other officers are members of the directorate of Lawson's Bay State Gas. William B. Spital promoted the deal and is authority for the statement that the machinery will be purchased and operations started in February.

NYE COUNTY.

The output of the Bullfrog district for 1908 is estimated to be \$910,480, of which the Montgomery Shoshone produced \$685,763.—Vandals attempted to destroy the orebins at the Mizpah shaft of the Tonopah Mining Co. Thursday of last week. Two charges of dynamite were exploded on the foundations, but failed to do any material damage. The motive of the perpetrators is not known.—The mines of Tonopah produced during the year 1908 a total of 286,926 tons of ore, estimated to be worth \$7,433,585 (figuring the milling ore at \$25 per ton and the ore sent to smelters at \$60 per ton). Of this total production the Tonopah Mining Co. produced more than half, or 169,090 tons.—The production of the mines of Tonopah for the week ending January 9 amounted to 5518 tons, of an estimated value of \$137,950.

STOREY COUNTY.

(Special Correspondence).—The Comstock lode is producing at the rate of \$20,000 per week, of which fully \$16,000 is coming from the Ophir mine. Most of the rest comes from the Consolidated Virginia.—At the Ophir ore is being extracted from the 2100, 2200, and 2300-ft. levels. The Ophir shaft is being repaired below the 1465-ft. point. On the 2300-ft. level the northeast and southwest drifts are progressing satisfactorily.—Ore running \$41.31 per ton is being taken from the 2150-ft. level in Consolidated Virginia. Some repairing and development work is going on at different points.—Considerable low-grade ore is being developed in the Savage and is being stored on the second-class dump. The average content is about \$4 per ton. It is coming from the Comstock Tunnel level.—The 1200-ft. level is being opened up at the Yellow Jacket and the surface tunnel is being repaired. The mill is running on fair-grade ore from the Crown Point mine.—On the 100 and 200-ft. levels of Silver Hill some fair-grade ore is being opened up and considerable development work is under way.—The lease on the Chollar croppings paid the company \$620 in royalties during November.—A larger air-compressor and about 350 ft. of larger pipe has been placed on the 2475-ft. level of the Ward shaft to furnish a greater supply of air to the electric pumps. Several repairs to the shaft have been made during the past few days. Owing to irregularity of the electric power supply, mainly due to storms and the blocking of the Truckee river by ice, resumption of sinking has been deferred.—Rumors of a rich strike in the Confidence and of important discoveries at other properties are freely circulated here, but have not yet been officially confirmed.—At the present time the Comstock presents more scenes of animation than has prevailed for many years, due principally to the successful unwatering of the Ward shaft.

Virginia City, January 9.

WASHINGTON

FERRY COUNTY.

The King Mountain M. & M. Co., of Spokane, operating claims on the State road near Boyds, is receiving a complete new outfit for the property. The company will resume operations at once with a force of 15 for the mines, together with a cooking outfit and a gang of men to make a road from the property to the State road, a distance of two miles. S. S. Bailey is president and general manager.—The

Michigan Gold M. & M. Co., a close corporation, has purchased from Spokane men three claims, an extension of the First Thought mine, in the Orient district, for \$30,000. The claims are known as the Climax, Moonlight, and Plutonic, and are on the extension of the famous First Thought lead. The property was purchased by capitalists of Michigan and Rosalia, there being 14 people in the corporation. No stock will be disposed of by the new company, which now has \$15,000 deposited in a bank in Spokane to carry on development work. The property was sold by M. B. Grieve, John Argall, Frank Weatherwax, and William Moore, of Spokane. The company has ordered machinery to carry on its development work. This includes an air-compressor and two drills. An adit will be started as soon as the machinery is on hand, and will be run to strike the main lead, which is expected to be reached in about 200 ft. The company is planning to start work within 60 days.

CANADA.

BRITISH COLUMBIA.

Phoenix, in the Boundary district, made a record for ore tonnage in 1908, despite the curtailed activity in development. This has been due to improved shipping facilities and increased tonnages from the Granby. Boundary mines shipped more than 1,500,000 tons of ore in 1908, as compared with 1,148,237 tons in 1907, and 1,161,537 tons in 1906, practically all of which was treated at Boundary smelters. Economy in mining methods now is shown in the fact that Phoenix mines, just before the slump in copper, were employing 1000 men and shipping between 90,000 and 100,000 tons of ore per month, while today from 750 to 800 men are employed in the camp and the tonnages are greater. Phoenix is the great copper camp of Canada, by reason of having the largest output of copper ore, and the Granby is the big producer, the other companies being the Consolidated Mining & Smelting Co. and the Dominion Copper Co. Total shipments from the Granby mines were 1,056,000 tons, as compared with 613,537 tons in 1907, and 801,404 tons in 1906. The smelter treated more than 1,000,000 tons last year, as compared with 637,626 tons in 1907 and 828,879 tons in 1906. The shipments from the Dominion copper mines, shipping to the Boundary Falls smelter, last year were as follows: Brooklyn, 5780; Rawhide, 10,740; Sunset, 3802; Mountain Rose, 530; Athelstan, 120. The smelter treated 22,666 tons. The Snowshoe mine of the Consolidated company, which resumed operations in August, is shipping 600 tons of ore daily. The greater part goes to the company's smelter at Trall and the rest to Greenwood smelter. Since resumption the Snowshoe has shipped 48,826 tons. The B. C. Copper Co. is the second big copper producer in the Boundary, and since resuming last June has been conspicuously successful in its operations. Mother Lode mine is the big shipper of this company, and now runs close to 2000 tons daily. Since resumption in June it has shipped 321,899 tons of ore to the company's smelter. The other mine is the Oro Denoro, three miles from Phoenix, which shipped 66,800 tons in the seven months. The company also owns the Lone Star and Napoleon mines, in Washington. The latter is shipping 100 tons daily. The B. C. Copper Co.'s smelter at Greenwood has had a successful seven months' run, the furnaces consuming 400,000 tons of ore. Other mines in the Boundary contributing ore shipments during 1908 are the Sally, 108 tons, and the Crescent, 53 tons, both high-grade properties. One car of 21 tons from the Sally mine netted \$3175 after paying all shipping and smelter expenses.

MEXICO.

OAXACA.

(Special Correspondence).—El Parian station, 60 kilometres north of Oaxaca, is the centre for a mining district of importance, there being some present activity. The Rio Seco, in charge of E. Chisholm, is preparing to erect a 10-stamp mill, with concentrating tables and cyanide vats. On this group are several parallel veins cutting through gneiss and schist, the ore being a gold-bearing quartz, having oxidized iron near the surface and iron sulphide at greater depth. There is 2200 ft. of development on one of the veins.

It is claimed the oxidized ore will average \$30 per ton, and that the sulphide ore will run 22 gm. gold in one vein, and 185 gm. in another vein. F. T. De Votie is president of the company.—The Santa Sofia M. Co. has a mine close to Caterina station, on the eastern slope of the Sierra Juarez. It is owned by two Boston men and is managed by Place & Elton of Oaxaca; the latter state that they have ore blocked out of the value of \$200,000, that the ore carries free gold which occurs as an impregnation along the fracture planes of the country rock, which is gneiss. Associated with the ore is an iron sulphide. The mine is opened by adit levels. The plan is to erect a mill on the property this year. The proposed plant will probably have a crusher, rolls, Huntington mills, amalgamating plates, concentrating tables, and cyaniding vats. It is said the unsorted ore of the mine will average one ounce of gold per ton.—The Santa Caterina adjoins the Santa Sofia and is developed by 2000 ft. of work. It has a 5-stamp mill in operation, the extraction being effected by amalgamation, concentration, and cyanide treatment. Arthur Buttner is superintendent.—The Socorro, near Parian, is developed by a 200-ft. shaft and 1000 ft. of lateral work. The ore contains free gold that assays \$10 to \$100 per ton, and to treat it a 10-stamp mill is being erected, John A. Morris of Oaxaca being manager.—The San Martín, controlled by Frank M. Leonard and associates, is situated 35 miles south of Oaxaca, on the Oaxaca & Ejutla railroad. In the course of development it is shipping ore that brings in \$5000 per month. The principal vein cuts through the diorite, and is 8 to 25 ft. wide. The ore contains silica 85%, copper 1, lead 2, zinc 2, iron 6, sulphur 7%. The shipping ore averages 80 gm. gold and 4 kg. silver per ton. The silver is mostly argentite, and the gold associated with it. There is said to be some sylvanite in the mine. The work is carried on through a 300-ft. shaft.—The Natividad, situated near the San Martín, is owned and operated by Manuel Miniaga of Oaxaca. He operates a 20-stamp mill, having amalgamating plates and pans, handling 50 tons per day. It is reported that equipment will be installed for cyaniding the tailing.—Los Ocotes mine, south from the San Martín, belongs to the Tezuitlan Copper Co., the development being in charge of Thos. Skewes Saunders. In the course of the development, however, a large tonnage of copper ore has been shipped to that company's smelter at Tezuitlan, in the State of Puebla. The Ocotes is opened through a vertical shaft 650 ft. deep, with much driving on the vein. It is reported that the workings expose 200,000 tons of ore in the mine, running 5% copper and 200 gm. silver per ton. The equipment includes a steam-hoist, air-compressor, and a generator for electric light.—The Conejo Blanco, in Taviche district, is in charge of Fred Whitaker. It has a vein of great width, which assays well in silver and gold. It strikes through an andesite country and has a quartz gangue. It is said to be under bond to an English company. The San Francisco, in the same district, is owned by the Tehautepec Silver Mines Co., represented by Judd Bros. of Mexico City. On the property are several veins, 4 to 10 ft. wide, with high-grade silver ore. Some shipments of hand-sorted ore have been made, but only development is now being done. The property is managed by E. J. Bumsted, and it is reported that a mill may be erected. It is owned by Juan Baights of Oaxaca, who ships regularly a sorted ore that assays 3 kg. of silver and 45 gm. gold per ton. The Escudora is opened by a 400-ft. cross-cut to the vein, on which there is 2000 ft. of development on one level. The ore is highly silicious, carries ruby silver, argentite, and some gold. The mine has been a producer for 10 years and is shipping now a small tonnage daily. It is owned in Oaxaca, and is in charge of Santiago Guzman.—The Oaxaca smelting plant is now in control of the Boston bondholders of the original company. It has one furnace for lead, and one for copper smelting, and is a well built plant. It is thought arrangements will be made to start it within a year. The Magdalena smelter, built for lead ores of the Magdalena mines in the Tlacolula valley, is under a receivership, the creditors being the Consolidated Metals Co. of Mexico City, having liens also covering the mines.

Special Correspondence.

WASHINGTON.

American Association for Advancement of Science. — Quartz Generated at Different Temperatures.—Geological Progress Meeting. —Study of Simple Sulphides.

Last week the centre of local interest was in Baltimore. At the meeting of the American Association for the Advancement of Science, the Geological Society of America, and various affiliated organizations, approximately 1500 scientific men assembled. Johns Hopkins University, most appropriately was the principal host, but the societies were scattered over the whole city, and many guests were entertained in Washington. The meeting was notable for geologists especially. With Thomas C. Chamberlin as president of the association, J. P. Iddings, the retiring, and Bailey Willis, the presiding vice president of Section E, and Samuel Calvin, the president of the Geological Society, a good meeting was assured. A long list of papers was read. The principal feature of the meeting was a symposium on correlation, participated in by Messrs. Van Hise, Adams, Walcott, Grabau, Weller, Girty, White, Williston, Osborn, Stanton, Dall, Arnold, Knowlton, Salisbury, MacDougal, and Chamberlin. This is the first time a comprehensive discussion of this subject has taken place since the 1891 meeting of the International Congress at Washington, and the papers presented served to show the greater growth of knowledge in the intervening time, while the great gaps were also brought out.

Papers on economic geology were not much in evidence, though J. T. Singewald, Jr., presented a brief summary of the results of an investigation of Maryland iron ores carried on last season for the Maryland Geological Survey. F. E. Wright and E. S. Larsen, under the title, 'Quartz as a Geologic Thermometer,' presented results likely to be of large use in a study of ore deposits. In brief, they said:

"Observations by Le Chatelier and Mallard in 1889-1890 proved that at about 570° quartz crystals undergo a reversible change, the expansion-coefficient, bi-refrindex, and circular polarization all changing abruptly. O. Mügge (*Neues Jahrbuch, Festband*, 1907, 181-196) has recently considered the problem again in detail, and by means of etch figures, combined with crystallographic behavior on heating, found that below the inversion point quartz crystallizes in the trapezohedral-tetartohedral division of the hexagonal system, while above 570° it is trapezohedral-hemihedral. The high form is similar to the low form, and differs chiefly in the fact of its common planes of symmetry. A plate formed above 570° is trapezohedral-hemihedral, but on cooling it changes to the trapezohedral-tetartohedral division, thereby losing its common planes of symmetry, which may then become twinning planes. It is to be expected, therefore, that quartz crystals thus cooled will be irregularly and intricately twinned after (1010.), while low temperature quartzes are simple or regularly twinned. It is furthermore evident, on considering the genesis of quartz at different temperatures, that intergrowths of right and left-handed quartz are limited chiefly to quartz crystals formed below 570°. These two criteria can be used to distinguish quartz which has been formed or heated above 570° from quartz which has never reached that temperature. The object of the present investigation has been to test the general validity of the theoretical conclusions on a number of quartzes from different kinds of rocks and veins, as well as to determine more accurately the inversion temperature."

Californians will be interested in the election of David Starr Jordan to the presidency of the Association, and the authorization given the council to arrange for a summer meeting in 1910 in Hawaii, if conditions prove favorable. A hearty invitation had been extended by Hawaii, a general committee having been formed, representing all the commercial, industrial, social, educational, and scientific in-

stitutions, with the Governor as chairman. The committee gave definite assurance of adequate halls, excellent hotel accommodations, and hospitable entertainment. The winter meeting is to be held in Boston.

Following the Baltimore meeting a conference was held at the Cosmos Club at Washington regarding the present progress of geology in America. It was called by George Otis Smith, of the Geological Survey, and included representatives of the Federal, Canadian, and several State surveys, and of various museums and universities. It is understood that the discussions were quite informal, and very frank. It is expected that much closer co-operation will result. Another evidence of a change at Washington is seen in the estimates of the Geological Survey made public January 1, of the production of copper, spelter, and lead in 1908. There was never any good reason why the Survey, rather than private individuals, should not compile these returns, which, of course, come from the various smelters. It had, however, never been done before. Waldemar Lindgren and E. W. Parker are to be congratulated, and it is hoped that figures for other materials may next year be given. It develops now that the damage from the fire a few weeks ago in the Survey building is less than was estimated. Congress is to make good the loss. Whether it will at the same time appropriate money for the needed fire-proof building is less certain.

The geo-physicists at the Carnegie Institution have taken up seriously the study of the simple sulphides. In view of the interesting results obtained from synthetical studies of the feldspars, and the great importance of the sulphides in ore deposition, mining engineers will doubtless welcome the news. Another piece of research, about to be undertaken, is a special study of calorimeters, which the Bureau of Standards is planning. This excellent institution is doing a large amount of good work which is too often overlooked. There are many problems relating to mining and metallurgy which it would doubtless be glad to study if the matter were properly brought to its attention.

LONDON.

Coal in Kent.—Messina Copper Mine. — Frecheville's Report. — Champion Reef.—Electrical Engineers.

Your readers probably hear vague news every now and then relating to the coal measures that are being exploited on the coast of Kent, close to Dover. There is a common supposition that the coal found here does not belong to the Carboniferous period, but that it is some more recent formation, such as lignite. The reason for this prevalent idea is that the workings are situated in a portion of England where the country consists of recent formations. In addition, not far away, ironstone and lignite used to be worked in the Wealden series from time immemorial. These ideas are quite erroneous, for the seams are portions of the true coal measures, and lie under the Cretaceous and other Secondary formations. They are found at considerable depth, and, judging from borings, they occupy a small basin perhaps 20 miles long and 5 miles broad. They have been traced under the English Channel, and it is probable that they are continuous with the coalfields in the north of France. It may be asked, why should these coal measures of problematical existence and at so great a depth through watery strata be so actively exploited. The answer is that the exploration was originally undertaken by Mr. Godwin Austen, a land-owner in Sussex, who was also a geologist. He was impressed with the theory that the French coal measures extended under the Channel and would be found in the southeast of England. His efforts were not crowned with success, for none of his borings ever passed below the Secondary strata. Some twenty years ago the subject was revived by Professor Boyd Dawkins, who encouraged Sir Edward Watkin, chairman of the South Eastern Railway, to utilize the abandoned Channel Tunnel works for the purpose. Sir Edward, seeing possible profit to his railway in the possession of a coalfield, supported the scheme and raised some capital. It is not necessary here to trace the

financial vicissitudes that overtook the venture after Sir Edward's death. Suffice it to say that two years ago an influential financial house pulled the scheme out of the mire, and the present board of directors includes a number of well known names in the coal world: for example, there are two of the directors of the Powell-Duffryn, which enjoys the reputation of being the most up-to-date colliery in Wales. At the present time the finances of the company are once more being put straight by the issue of new preference shares. The sinkings are on the seashore under the Shakespeare cliff, between Dover and Folkestone, and adjoining the line of the South Eastern railway between these two towns. There are two shafts, the first of which cut a coal seam at 1273 ft., and has passed through five others, the sixth being at a depth of 1614 ft. Bore-holes driven below this depth have intersected four other seams, the lowest being at 2221 ft. The other shaft is not down to the coal measures yet, and will be eventually used for hauling purposes. Driving has been done at the 1273-ft. level and some of the coal brought to the surface. It is a friable bituminous coal. The seams are mostly thin ones, being from 1 ft. to 2 ft. 9 in., with the exception of that at 2221 ft., which is 4 ft. thick. The intention of the company is to sink at once to this seam. Both of the shafts are circular, the first being 14 ft. diam., and the second 18 ft. They are tubbed with iron casing and concrete backing, the first shaft to 1600 ft., and the second as far as it has been sunk. Below 1600 ft. the first shaft is lined with brick and cement. Whether the venture will ultimately succeed or not remains to be seen. All that I can say is that the present board will make it a success if anybody can. A notice of this subject is not complete without reference to another company, which is also working on the coal problem near Dover, at Waldershare, Tilmanstone, and elsewhere,—but, as Kipling says, that is another story.

A year ago I wrote about the Champion Reef mine, at Kolar, India, and mentioned how this famous gold-producer had fallen off during the last year or two. Since then the exploration work has brought no bright ray of hope in the way of new discoveries of ore. For years the average content of the ore treated was well over an ounce per ton. Now they have fallen to 13 dwt. In addition, the amount of ore treated has been decreased and the ore reserves have been depleted. During the year ending in September, 172,006 tons of ore yielding 10.8 dwt. per ton and 231,101 tons of tailing yielding 2.5 dwt. per ton were treated, and the total production was 122,562 oz. bullion, which realized £466,172. Three years ago, when the mine was at the height of its glory, 215,167 tons of ore and 177,000 tons of tailing yielded 216,802 oz. bullion, realizing £825,263. It has not been possible to reduce the costs of operation to make up for the decreased value of the ore, so that the working profits have been greatly reduced. During the past year the profits were £143,938, out of which £52,000 was distributed as dividends and £65,000 written off capital expenditure incurred in sinking new shafts and erecting new plant. The dividend looks small, compared with the £416,000 distributed three years ago. The prospects of the Champion Reef mine do not look hopeful at present, but it need hardly be said that John Taylor & Sons, the managers, are not the people to be easily discouraged.

The Institution of Electrical Engineers has just acquired a handsome building on the Thames embankment for its permanent home. American visitors to London will probably remember the solid looking red brick building standing between the Savoy Hotel and Waterloo bridge. Its uses were never well known to the tourist or visitor, or for that matter to the Londoner himself. It belonged to the Colleges of Physicians and Surgeons conjointly, and was chiefly used as an examination hall. In future it will become better known to engineers. The Institution of Electrical Engineers has hitherto been content with a suite of offices on Victoria St., Westminster; these have become far too cramped for the growing body with its membership of over 6000, and it is now following the lead of the two older institutions, the Civil and Mechanical Engineers, in securing adequate

accommodation in a building of its own. The Institution of Civil Engineers has been domiciled on Great George St. for many years, and not long ago re-built its premises in a handsome style. The members of the American Institute of Mining Engineers who visited this country two years ago will remember the building, as their joint meeting with that of the Iron & Steel Institute was held there. Unfortunately this building is to disappear before long, or to change hands, as the adjoining Government offices require the site for their own purposes. The Institution of Mechanical Engineers erected a building for themselves ten or more years ago, not far away, overlooking St. James Park. The Institution of Electrical Engineers was founded in 1870 as the Society of Telegraph Engineers, and William Siemens was the first president. Electricity was an unimportant affair in those days, and at the end of the first year the membership only numbered 110. By 1878 the numbers had grown to 1000. In 1881 the name of the Society was changed to the Society of Telegraph Engineers and Electricians, a change which was rendered necessary by the introduction of telephones, arc lights, and dynamos. Its present title was adopted in 1889. The list of presidents is a distinguished one, including as it does the names of Kelvin, Hopkinson, Swan, Crookes, Sylvanus Thompson. The Institution in its new home will continue to expand and flourish. One of these days, when the various English societies dealing with mining and metallurgy are amalgamated, as they should be, the mining interests of Great Britain will be represented by a strong institution with a handsome home of its own.

Some months ago, when writing of the development of copper deposits in South Africa, I mentioned the Messina mine in the northern Transvaal and promised to give some information about it at an early date. The present time is opportune for doing so, as R. J. Frecheville has just returned from making an examination. His views and opinions are of great interest. Briefly, he says that though the mine is extensive and the ore rich, it will prove unprofitable to work until there is better railway communication and a smelter on the spot. The Messina mine is situated 130 miles north of Pietersburg, which is at present the northern terminus of the Central South African railway. The company owning the mine, called the Messina Transvaal Development Co., of London, under the control of Chaplin, Milne, Grenfell & Co., is urging the Transvaal government to continue the line from Pietersburg to Messina, and thence forward another 100 miles to West Nicholson, where it would join the Rhodesia railway. For the last two years the ore has been hand-picked and mechanically concentrated, yielding 120 tons of concentrate per month averaging 60% copper. This is shipped to England. A year ago with copper at £100 per ton a profit was made, but nowadays, when it is down to £60, even this rich ore cannot stand the cost of transport. Mr. Frecheville recommends that operations be suspended until a railway is built, and that the company provide £100,000 properly to equip the mine and build a smelting and converting plant. The ore deposit is interesting and has been worked along the surface for quite five miles at various places by pre-historic metallurgists. The formation consists of gneiss and granite traversed by basic dikes. The ore is found in veins occupying fractures along a zone of shearing and crushing. The width of the mineralized belt is from 500 to 1000 ft. The lodes vary from 2 to 10 ft. in width. At the point where most development has been done, the old workings extend to 50 ft. below the surface. Further development by the present company has gone down to 300 ft. and has shown the existence of five defined lodes, nearly parallel, over a width of 600 ft. The orebodies are of irregular shape and consist of stringers, leaders, and bunches of chalcocite, bornite, and chalcopyrite in a gangue of crushed country rock with some quartz. From the beginning of operations up to the end of last September, 12,543 tons averaging 17.7% copper has been extracted from the mine, and from this 2541 tons averaging 60% copper has been sorted out and shipped. Some of the tailing has been stacked for future treatment, also some middling, and further supplies of low

grade ore have also been placed on the dump. A concentrating plant to treat 50 tons per day was started in the summer, and during July, August, and September, this produced 344 tons of concentrate, averaging 59.5%, from 3441 tons of 10% ore. This is an extraction of only 60% of the copper content, but if it was not necessary to make so high a grade of concentrate, the extraction could be greatly increased. Mr. Frecheville estimates that the developed ore reserves are about 50,000 tons of 15% copper and he considers that there is every encouragement to expect further developments in depth and also laterally. He points out that the chalcocite and bornite are probably surface enrichments and will turn to chalcopyrite in depth, though there is no indication of this change so far as the workings have gone up to the present time. He is strongly of opinion that the rich ore should not be wasted in the present unprofitable manner, but should be conserved until such a time when it can be treated at a profit; therefore his recommendation to wait for railway communication, and in the meantime to develop the mine and erect smelting plant.

The Sulphide Corporation, which owns the Central mine at Broken Hill, with smelting works at Cockle Creek, is now getting better results, the new mill erected over a year ago being operated more efficiently. During the first six months of the present year, 100,943 tons were treated, yielding 18,591 tons of lead concentrate and 32,312 tons of zinc concentrate. The assay of the lead concentrate was 33 $\frac{1}{3}$ oz. silver and 61.2% lead and the extraction was 45% and 70.5% respectively. During the second half of 1907 the extraction was only 42.5% and 66.8%. The duty of the plant has been still further increased, for during the 20 weeks from July to November, 1908, the extractions have been increased to 47.2% and 76%. The zinc concentrate produced during the first six months of the present year averaged 40.9% zinc, 12.5% lead, and 17.8 oz. silver and the extractions were 74.7% of the zinc and 72.3% of the silver. This is a considerable improvement over the previous half-year, when the extraction of zinc was 69.4% and the silver 61.8%. The extractions have been further improved, and during the 20 weeks specified the extractions have been 85% and 76.5% respectively. In addition to the above production, which all came from mine ore, 54,254 tons of zinc tailing from old dumps were treated during the first six months of 1908, and 19,545 tons of zinc concentrate was produced, averaging 14.4 oz. silver, 10.4% lead, and 44.2% zinc, the extractions being 79.6% of the zinc and 71.9% of the silver. Since then the extraction has risen to 82.3% of the zinc and 76.6% of the silver. The financial results for the year ending in June have been unfavorable, owing to the fall in the price of metals, and the net profit was only £8549. As there was a balance of £79,242 brought forward from the previous year, the directors have been able to pay £55,000 as 10% dividend on the preference shares. The ordinary shares get nothing. It is not quite clear how the company will be effected by the recent judgment against the Ballot-Sulman-Picard flotation process, which is used by this company for producing zinc concentrate.

BUTTE, MONTANA.

Copper Output in 1908. — Mine Ventilation. — The Snowstorm. — Raven. — Calumet-Corbin.

During the calendar year of 1908 the Butte mines produced 269,165,640 lb. copper, an increase of 20,278,124 lb. over 1907. The height of the financial panic and depression in the copper industry was reached in the latter end of 1907, and many of the Butte mines were closed and remained so until March 1, 1908, after which operations were gradually resumed. About June 1, when the industry in Montana was again demoralized by tremendous floods which did damage to railroads, mines, and smelters, and so crippled the smelter of the Boston & Montana Co. at Great Falls that it was not repaired and restored to full operation until about November 1. Prior to that date the Boston & Montana Co. mined a limited amount of ore and shipped to the Washoe smelter at Anaconda for treatment. The

high mark of production was achieved in 1906 when the Butte mines produced 342,688,809 lb. of copper. The following table shows the total copper production in pounds of the various companies during 1908, compared with the production of 1907:

Companies.	1907.	1908.
Boston & Montana.....	63,053,655	77,010,800
Anaconda	64,154,636	67,064,000
Butte & Boston.....	9,209,650	10,349,640
Washoe	6,438,420	8,569,170
Parrot	5,403,010	6,281,080
Trenton	6,794,475	6,229,940
North Butte	29,534,240	38,526,480
Butte Coalition	24,971,800	21,488,580
Original	17,296,940	24,936,700
Pittsburg & Montana.....	4,785,090	4,295,100
East Butte	3,965,480
La France	2,168,975
Miscellaneous	3,111,145	4,414,150
Totals	240,887,516	269,165,640

The problem of mine ventilation in the Butte district has for years been a serious one, and although it has been agitated in the press and by the miners, the State has not yet adopted a law making the introduction of proper systems of ventilation compulsory. Whatever has been done in the way of improving conditions has been done through necessity in mining operations and not directly for the benefit of the miners. Some of the mines in Butte are insufferably hot, and only the lower grade of foreign labor can be induced to work in such places. The State mining inspector urges a law compelling companies to sink independent shafts for air, separate for each mine. Ventilation in the mines of the Amalgamated has been greatly improved by a system of drainage tunnels through which the water from the mines is drained to a central pumping station, avoiding the necessity of pumping plants in the different mines, and thereby reducing the temperature. At the Leonard mine a new development shaft is being sunk; as soon as connections were made at the 1500-ft. level with the other workings the temperature of the mine was reduced 20°. Similar results followed a connection with an air-shaft of the Pennsylvania mine at the 1200-ft. level. The question is again being discussed in the Montana legislature.

According to the annual report of the Butte Mining Stock Exchange, the only dividend-paying stock traded in on the exchange is that of the Snowstorm Mining Co. Not another stock is even within hoping distance of dividends. The Snowstorm has just declared another monthly dividend of 3c. per share. It is the fourth monthly dividend paid since the company resumed after a long suspension of operations during the financial depression. The company is shipping between 600 and 700 tons of ore per day, the cost of mining and delivery at the railroad not exceeding \$1.40 per ton. Its return on shipments during December and January have been from 8 to 10% copper, with about 6 oz. silver per ton. A number of diamond-drill tests have been made, and the big insiders have been buying stock on the market, paying as high as \$2.35 per share for it.

The Raven Mining Co., which is engaged in sinking a shaft, is cutting a station at the 1300-ft. point. The shaft is an incline, and the bottom has a vertical depth of 1100 ft. The lowest level is at 1100 ft., but a winze 100 ft. deep has been sunk from that level. The shaft will be sunk to 1600 ft. and another cross-cut driven to the veins.

The Calumet-Corbin Mining Co. has been incorporated under the laws of Michigan by Butte and Michigan men for the purpose of taking over and operating the old Minnesota mine in the Wickes-Corbin district. The company is capitalized for \$1,500,000, divided into 150,000 shares of the par value of \$10 per share. Twenty-five years ago the Minnesota produced considerable silver, lead, and gold. It is opened to a depth of 300 ft., where the ore shoot is 500 ft. long and from 2 to 5 ft. wide. The company has started to sink a two-compartment shaft.

JOPLIN, MISSOURI.

Production of Lead & Zinc in 1908. — Extensive Development. — Kansas Field.—Great Orebodies in Oklahoma.

The lead and zinc fields comprising the Joplin district, embracing a portion of three States, Missouri, Kansas, and Oklahoma, showed a small decrease in tonnage as compared with the year 1907, in both lead and zinc ores. The decrease in zinc ore was 27,000 tons, while the value of the zinc production for 1908 was \$3,604,440 less than that of the production of 1907. The 1907 record for the output of lead ore was 2913 tons more than for 1908. The value of the ore for 1907 was \$745,509 more than for 1908. The following table shows the tonnage and value of both ores in the three States for the year 1908:

State.	Pounds Zinc.	Value.	Pounds Lead.	Value.	Combined Value.
Missouri.	439,889,384	\$7,625,370	67,771,722	\$1,862,380	\$ 9,487,746
Kansas.	57,803,725	1,009,203	6,996,087	195,928	1,205,131

The average price of all grades of zinc ore for 1908 was \$34.50 per ton, which was \$9.28 less than the average price for 1907. The average price per ton for all grades of lead ore was \$55.03, which fell below the 1907 record by \$13.86.

Prospecting With a Drill Near Joplin.

From this it can be seen that zinc ore fell off 21%, while lead ore has fallen off 20%, from the prevailing prices of the previous year. During the same period the tonnage of zinc ore was decreased 9.4 and the tonnage of lead ore 6.7%. During the latter part of the year a heavy increase in production from the 'sheet-ore' mines was noticed because of the advance in the price of ore. These properties were idle during the period when zinc-ore sold below \$38, but began activity as soon as the price reached \$40. It was owing to this greater activity that the district was enabled to approach so closely the record for 1907. A number of mining centres increased their production for 1908, among which were Webb City, Carthage, Spring City, Sarcxie, Carl Junction, and Zincite in Missouri, and Miami and Quapaw in Oklahoma. A notable feature of the increase in production was the greater tonnage of low-grade ore. The principal increase in Spring City and Sarcxie was in silicate ore, while in the Oklahoma districts it was low-grade zinc-blende. In Miami the ores ran as low as 45% zinc, with an iron content of 6 to 12%. The increase in Carthage and Carl Junction was due to high-grade zinc-blende. Loss in tonnage was noticed in Alba, Joplin, and Duenweg in Missouri, and in Galena, Kansas.

Missouri led in the production of both lead and zinc during the past year. A large addition of new mineralized territory was opened during the year, especially in the

eastern portion of the field. A large amount of prospecting and development has been done at Sarcxie and Carthage, so that these two almost doubled their output during the year. The new territory extends the Sarcxie belt eastward to Wentworth and westward to Carthage. Southwest of Sarcxie during the latter part of 1907 a large amount of prospecting was done, demonstrating a great extent of ore-bearing territory. Development ceased with the panic, and it was not until the middle of the past year that active development was again begun. The most notable feature of interest at Carthage is the renewal of activity on the old Porter tract in the northwest portion of the city. Development has also extended across the river northwestward, where the largest production for this district was noted. These new properties are now well developed and will be ready for new mills during the early part of the year. This territory was formerly considered outside the mineralized zone. Many drills have been at work at Alba and Neck City and these have found ore in all directions. Some of the best lead and zinc deposits of the district have been found here. Five miles south of Joplin lies Spring City, which largely increased its production during the year, and extended its territory through extensive prospecting and development. The district has been especially fortunate in its large rich lead deposits recently opened. Five concentrating plants will be added

here in the immediate future on properties which produce high-grade lead and zinc. At the present time the principal production is zinc silicate. New developments have also been made at Granby and Seneca, still farther south. These will add a large tonnage to the output from the district in 1909.

One of the most surprising increases during the year was the large production in the Webb-City-Carterville zone, which is the centre of the 'sheet-ore' area. Most of the large mills in this belt were idle during the greater part of the year because they could not produce at a profit at the prevailing prices. For this reason a decrease in production was expected, but during the latter part of the year, when ore passed the \$40 level, a number of the larger plants resumed operations, and when the statistics for the year were compiled

it was found that the district had surpassed the 1907 record by 2000 tons.

There was a decided decrease in production for the Kansas field during 1908, owing to the effect of the panic, but during this period a large amount of prospecting and development was done, extending the proved area in several directions. The principal addition to the Galena field was made by the Clermont Mining Co., south of the city, which has recently completed twenty drill-holes and has a number of shafts already well started on this virgin land. This company has added 500 acres to the productive mineral territory of Kansas. An important feature of the development has been the discovery of ore deposits at deep levels. North of the city an ore stratum was found lying between the 222 and 300-ft. levels. The ore-bearing rocks lie much deeper here than in the Joplin district. Extensive development is planned for the coming year in all these new fields. At Cave Springs an incline shaft is taking out ore at a deep level, the shaft being 440 ft. deep. The deep-ore levels have been demonstrated on about 120 acres north of Galena. In the Badger-Pearcock district, lying north of Galena, the production fell off last year, but a considerable amount of development has been done extending the known mineral area. Two new plants have been added.

The new lead and zinc fields of Oklahoma have made the greatest strides of any in the past year. The extension

of the Miami field has been enormous. During the last three quarters of the year the production here was 6500 tons of zinc-ore and more than 1000 tons of lead ore. There are at present nine concentrating plants actively at work here, while at least four others are being built, or will soon have let contracts for construction. The excessive richness of the ore so far opened is the explanation for the large production from so few mills. This ore runs from 10 to 30%, greatly in excess of the 'sheet-ore' deposits in the Joplin and Webb City districts.

The greatest difficulty in the new field has been the concentration of the ores because of the oil and bitumen found in some strata of the deposits. The difficulty in concentration decreased the grade of the concentrate, making it from 45 to 52% zinc, with an iron content ranging from 6 to 12%. When this ore, impregnated with oil and bitumen, was treated in the jigs it had a tendency to float off the fine in the overflow and to carry over the concentrate mixed with the bitumen and gravel into the tailing. Thus the tailing piles became rich in ore running from 6 to 20%, or richer than the original ore at many of the older mines. Much advance has been made in the milling practice by the later mills, and some of these now produce a concentrate running as high as 56%, with an iron content of only 2%. The loss in tailing has also been decreased.

DAWSON, CANADA.

Mild Winter.—Dominion Creek.—Method of Working.—Lost Pillars.—Quartz and Sulphur Creeks.

Some of the mildest weather experienced in years has been the rule for the past month; this has had a tendency to retard winter work in some parts, but on the whole operations are well under way. In traveling along the creeks, one sees here and there dumps gradually assuming considerable size; these bid fair to be up to the average of former years when the spring clean-up takes place.

There is more work being done in the vicinity of Granville, on the lower end of Dominion creek, than anywhere else in the Klondike. The creek at this point is half a mile wide, and pay is found from rim to rim. The gravel is known as White Channel, and consists chiefly of well washed quartz; there is so little other material in the gravel that the tailing gives one the idea of being entirely quartz. The gold lies on a false bottom composed of variously colored clays; on this clay and for six inches to one foot above, the gold is found. This deposit has a value of $2\frac{1}{2}$ to 3 cents per pan, and the gravel that must necessarily be removed is worth from \$2.50 to \$2.75 per cubic yard.

The method of operation in this locality is distinctive, a shaft of the usual dimensions—4 by 6 or 6 by 8—is sunk to a depth of 8 ft. in the clay bottom, thus forming a sump below the general level of the pay-gravel; this sump is filled with water, and is the source of supply for a pulsometer pump, placed slightly above the top of the water, which is kept warm by the steam necessary to run the pump. The water is delivered to the face of the drift, usually through canvas hose, where it is played against the frozen gravel, gradually thawing and caving the ground, in much the same way as similar work would be carried on above ground. When sufficient gravel has been caved and thawed, the pump is stopped, and men are put to work with pick and shovel; the gravel is then put into cars, run to the shaft, and there hoisted and piled in mounds at some convenient point on the surface to await the natural thawing of spring, when the gold will be extracted in the usual manner, namely, by sluicing. It is these mounds of dirt that we call 'dumps'. The method just described is found particularly effective, for the reason that no steam is necessary in the drift, such as would cause continuous sloughing of the roof and the handling of quantities of waste; it is also found that it is an easy matter to keep the roof properly arched where it is necessary, as is frequently the case, because the fineness of the gravel and lack of moisture make this deposit much more difficult to manage than the ordinary creek-gravels of this region. Practice has demonstrated

that the gold extraction is clean, and the total cost of production is reduced to the lowest point yet attained in this district.

At the upper end of Dominion creek, considerable winter work is under way, but not on as large a scale as at Granville. Here are seen many small dumps, the work of one to three men, usually working with a hand-windlass. This kind of work is made necessary by the generally chopped-up condition of the creek. The claims have all been heavily worked in past seasons, so that the ground remaining that can be worked by the old method consists of pillars and bed-rock that has been carelessly cleaned. These pillars are usually rich, being in the middle of the pay-channel; they were left behind by former workers after they had served their purpose, and were surrounded by waste. Strange as it may seem, it is a rare thing to find a claim-owner that has

Part of the Yukon Territory, Canada.

a positive knowledge of the position of such pillars; he only knows vaguely where they are, so that much money and time is frequently lost in finding such pieces of ground. A simple method of plotting each year's work when finished, would have been the means of saving money, time, and annoyance to most of the claim-owners of the camp. It would be well for those in the newer camps to adopt some such method, to avoid a repetition of this unsatisfactory state of affairs. Eldorado, Bonanza, and Hunker creeks are no exception to this failing, and the Yukon Gold Co. is going to reap the benefit; there is little doubt that these pillars will materially increase the value per cubic yard in all of the creek-bottoms that they control, beyond the estimate that they have placed upon them.

Quartz creek at the upper end is also a busy place; many dumps are well under way, and good results can be relied on, when the spring wash-up takes place. Sulphur creek is also hard at it, and some particularly good dirt is being hoisted on claims numbering in the forties Below Discovery. A fair amount of prospecting work is going on, at the lower end of this creek, with encouraging results. Reports are in circulation regarding districts that are farther away, but

it is too soon to form any opinion of their worth. Haggard creek is supposed to be doing well; this is a tributary of the McQuesten river and bids fair to become a producer of importance in the future. General business is good.

TORONTO, CANADA.

Farcical Enforcement of Anti-Wild-Cat Laws.—Gowganda Withdrawn from Prospecting. — New Road. — Dividends and Developments.

Apparently the stringent Ontario laws for the prevention of wild-catting by means of publicity are being enforced in much the same perfunctory fashion as the prohibitory laws in various States, where the fine occasionally or periodically levied on offenders after allowing them to run for a time with impunity, practically operates as a license to break the law. Provincial Secretary Hanna was loud in his promises to make an example of offenders, a number of companies were prosecuted, and the net result up to date is that four companies have been fined \$200 each. These were the Crown Jewell, the Gifford, the Gifford Extension, and the Otisse. How easy the law-breakers have been let down can be understood when it is borne in mind that the penalty for false or defective prospectuses is a fine imposed upon each director of the defaulting company of between \$50 and \$400. The prosecution in these cases was instituted against all of the directors who could be reached, but after the infliction of one fine in each instance, the proceedings against the other directors were dropped. It is hard to see how, by any stretch of the imagination, the prospect of a \$200 fine can be supposed to act as a deterrent upon a concern that is daily raking in thousands from credulous investors. It is petty as compared with the bulk of promotion expenses. The latest phase of the farce is the agreement between the Crown prosecutor and three of the companies, to submit a stated case to the magistrate, and should he then make a formal conviction, to carry the matter to a higher court. In the meantime, though wild-cat advertisements have largely disappeared, for which perhaps the holiday season and a break in the stock-market are responsible, the wild-cat promoters have taken to operating through the mails, and are sending out circulars, heedless of the warning that this is also against the law. Whether it is or not, or whether the law has any effective force, may be known in a year or two, when the higher court and the Court of Appeal have rendered decisions.

The Provincial Government of Ontario has issued an Order in Council withdrawing from prospecting a large area in the Gowganda district. This comprises, in addition to Haultain and Nicol townships, and two other unnamed townships, covering about 144 square miles, the bottoms of the lakes and a strip of land 66 ft. deep on the shores surrounding the lakes. This affects lakes Gowganda, Everett, Bloom, Miller, Le Roi, Wigman, and other bodies of water. A large area in the townships withdrawn has already been located by prospectors, and lakes Miller and Le Roi have also been covered, and some water claims made on Gowganda. All claims staked before December 18 are exempted. The purpose of the Government is to offer the properties for sale subject to royalties, as in the case of Cobalt lake. The most urgent matter before the Government in connection with northern Ontario mining interests is the opening of transportation facilities to Gowganda. The building of a wagon-road from Sudbury, 80 miles distant, has been undertaken by Mackenzie & Mann, of the Canadian Northern railway, on account of the Government, in conjunction with the town of Sudbury, that being the natural base of supplies for the district. Operations have already been commenced by a large force of workmen. The road is expected to be complete early in the New Year. Mackenzie & Mann have also in view the extension of the Canadian Northern Ontario railway into the Gowganda district from Burwash lake, and have put a survey party in the field.

There has lately been a seasonable dulness in Cobalt stocks, varied by a slight revival during the last few days as the result of satisfactory dividend declarations, and the influence of the New York market. A considerable advance

on present prices is anticipated early in the new year. Nipissing has announced its regular quarterly dividend of 3% and an additional bonus of 2%. Some new finds of an encouraging character have recently been made on the property. A new vein was found in cross-cutting at the 75-ft. level from the Fourth of July shaft; the vein is 3 in. wide, yielding high-grade ore. At the 145-ft. level of the Kendall shaft, a new cross-vein was found, from 3 to 8 in. wide. The La Rose No. 3 vein, on which a shaft is being sunk, has widened to 4 in., yielding over 5000 oz. silver per ton. This vein has a length of 600 ft., and a portion of it has been developed by open-cut mining. A rich vein recently cut on the O'Brien runs into the La Rose parallel to the No. 3 vein, and will be worked by the latter company from No. 3 shaft. The new plant of the Temiskaming is on the ground, and partly erected. Two 100-hp. boilers are set up, and also the

Map Showing Position of Cobalt and New Districts in Ontario.

bed-plate of the new compressor, and it is expected that the plant will be in operation in two weeks, when considerable new ground will be opened. A new shaft has been started on the Duchess on the new vein near the Gifford Extension, and is now down 14 ft. The Kerr Lake Majestic will begin operations under the direction of William Powell, managing director, with an up-to-date plant, comprising a 12-drill air-compressor and boilers. The Cobalt Central is enlarging the capacity of its big concentrating mill, and will treat custom ore, having already made some contracts with adjacent mines. Shipments of silver to New York amounting to two tons were made this week from the Coniagas smelter at Thorold, Ontario.

The prize of \$100 offered by J. B. Tyrrell, mining engineer of Toronto, for the best collection of Ontario minerals made during the past season, has been awarded to W. F. Battersby of the Kingston, Ontario, School of Mines.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The import duty on lead ore is $1\frac{1}{2}$ cents per pound, on pig lead it is $2\frac{1}{8}$ cents per pound, and on white lead $2\frac{7}{8}$ cents.

Graphite on the Pacific Coast would need to be of superior quality to find a market. Only crystalline graphite would be available; the amorphous variety not being in demand.

Assessment work is not required on a mining claim for the year within which the location was made. It makes no difference whether the location was made on January 1 or December 31; the law is clear on this point.

Molybdenum is present in the lead molybdate mineral wulfenite with many gold ores in the desert regions of the Southwest. It does not interfere with amalgamation. Molybdenite is a quite stable sulphide, not readily oxidizable, and is innocuous in gold milling.

Shaking plates for amalgamation are advantageous with certain ores, but they do not necessarily give better results than stationary plates. They effect an even distribution of the pulp, and by checking the flow they facilitate the settling of gold upon the amalgamating surface. It has been claimed that shaking plates keep brighter and require less frequent dressing, but except in individual cases this does not seem to be borne out in practice.

The statement that the Katanga ores contain a gangue "absolutely infusible at or near the melting point of copper" is misleading. All that is meant is that the gangue is deficient in base. The so-called 'reduction method', involving a treatment that will reduce the copper to the metallic state, after which it may be crushed and concentrated mechanically, is quite undeveloped in a practical way. Indeed it is wholly improbable that an economical separation can be effected by such a process.

Timber in a flooded mine, even after 20 years or more, will be found intact and temporarily unimpaired, but after exposure to the air it is speedily affected by decay. The condition of the mine-workings will depend upon many factors. In general the processes of decomposition of the ore and bounding country will be arrested by the flooding of a mine, but if much soft ore, or clay and sericite, such as the miner includes under the misnomer 'talc', be present, it will often be found that it has softened and flowed in large quantities into the drifts.

Failure to perform assessment work on a mining claim for any year except the year within which the location was made leaves the ground open for re-location. The courts hold, however, that unless the title has been extinguished by adverse location by

some other person, the original locator's title may be re-established by resumption of work. The alternative of re-location is also open to the original locator, but if palpably done to avoid performing assessment work the title would be less secure against adverse claimants than it would have been by simple resumption of work.

Many metals and alloys used in the industries owe their valuable properties to the fact that they are in a state of unstable equilibrium at ordinary temperatures. Hardened steel, for example, tends to revert to the condition of soft steel at all temperatures below 700°F ., and block tin is slowly converted into a gray powder, consisting of metallic tin, not a compound, at temperatures below 68°F . Polished cast-tin when inoculated with a little gray tin is rapidly changed and exhibits dull patches, which spread at the rate of several millimetres per day. The same rapid deterioration is shown by certain alloys of tin and aluminum, which also disintegrate into powder. These alloys break up after a few months, but the cause is probably to be ascribed in part at least to oxidation.

Where a junior location of a mining claim has been located across a senior location so that the junior claim is divided into two separate parts by the senior claim, it is now permissible for the junior claimant to maintain his title to the two non-contiguous segments by virtue of a single location, and he may obtain a patent for such a claim, though the patent would necessarily reserve all property rights pertaining to the senior claim. Prior to the Del Monte deci-

sion by the United States Supreme Court, the junior claimant was either compelled to elect which of the two disconnected parts he would take, or the entry was confined to that part containing his discovery. The Del Monte case decided that a junior locator might place his end-lines upon a senior claim, and the Land Department now permits a junior locator to lay his lines entirely across the senior claim, so as to include surface territory not covered by the senior location.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

National Bureau of Mines.

The Editor:

Sir—In the issue of December 5 I see an article on this subject. A perusal of it shows that the author of it has been connected with some kind of government bureau in the past, and appears quite content to remain in such a bureau for the present or the future. This being the case, we find, in general with those who have become part and parcel of a bureau, that he considers the correct solution of every problem in any way affecting the welfare of humanity to be the work of a Government bureau; and that the answers to all these momentous problems should be in the reports of such a bureau.

The nine problems that were cited are doubtless of a more or less pressing nature wherever mining or metallurgical operations are carried on; but a close analysis of many of those propounded is evidence to me that they are not from a trained engineer. Take, for example, the first problem: "A systematic investigation of underground methods of work carried on from camp to camp, with a view to a formulation of the exact conditions under which each method is applicable." Think of a Government bureau, constituted largely of a class to which in the West we apply the term "kid-glove miners," formulating plans for the successful operation of mines by *a priori* methods! These are problems that anyone familiar with the very rudiments of mining knows cannot be reduced to a formula. Mining is both a science and an art, and requires for its successful solution the application of both brains and experience.

The second problem has still less to recommend it as a basis for erecting a Government bureau and publishing long reports on this subject. The problems of hauling and hoisting have been exhaustively treated in three or four different languages, in books devoted to mining, and in many excellent periodicals. No tedious 'padded' Government reports from a Mining Bureau are necessary to enlighten those who are really interested in this phase of the question.

As to the third problem, what great benefit would gold and silver metallurgists be likely to derive from a study of the subject as set forth in a Government report? I would say: less than he would easily be able to gather from one of a number of first-class publications on the subject, or what is better: a careful digest of recent literature such as will be found in the *Transactions* of the American Institute of Mining Engineers, and the files of your own valued paper, and others that could be cited.

Thus we might go on; but the first three problems proposed, when examined, seem to be fundamentally wrong. Why? Simply this: the successful solution

of every mining and metallurgical problem (or any other problem in engineering where man's intelligence must direct the forces of Nature to gain a desired end), involves the consideration of many factors, no two of which are likely to be the same in different places. If this were not so, engineering could not be called a profession, and the hundreds of young men who are today preparing themselves for work in engineering fields would have little to look forward to, if the proposed aims of the Mining Bureau should be faithfully carried out.

Whatever the specious pleas may be (and they are many and varied, as everyone knows) for the establishment of a Mining Bureau, we may rest assured that, if once established, few of the promises will be fulfilled. The great work of our mining and metallurgical world, the most important discoveries, the most useful applications of science, will continue to be made in the future, as in the past, by private and individual initiative, pluck, skill, and money. One Government bureau, more or less, will perhaps make little difference; the money necessary to support it will be drawn from so many that the increased burden is not felt; the valiant ones who have fought to establish it will be rewarded by positions of one kind or another, and the results, in many cases of doubtful value to the public, will possibly afford valuable exercise to those engaged in getting out the reports.

In my opinion, it is time the engineering profession as a whole, and especially the mining and metallurgical branch of it, should resent any further encroachments upon its legitimate domains by the enlargement of present Government bureaus and the establishment of new ones.

ROYAL P. JARVIS.

Knoxville, Tennessee, December 15.

Cost of Electric Pole-Line.

The Editor:

Sir—In answer to the request of your correspondent I am pleased to submit the following figures, showing the cost of constructing one mile of pole line in the Atlin, B. C., mining district, which was carried out by the Western Engineering & Construction Co., of San Francisco:

42 poles are required for 1 mile.	
42 poles, 8 in. at top and 26 ft. long, delivered on ground	\$ 84.00
Cross-arms, 3 by 5 in., 48 in. long.....	21.00
Insulators and pins, 126 each.....	94.50
3 lines No. 6 wire, 1152 lb., at 15c.....	172.80
Engineering expenses	26.00
Post holes; all tools furnished by the company; average over a 10 mile line, including powder and drills for blasting many holes; holes 5 ft. deep.....	63.00
Peeling poles and fitting cross-arms.....	31.50
Setting up poles and tamping	42.00
Stringing wire	42.00
Paraffine for dipping pins and cross-arms...	7.14
Distributing cross-arms, insulators, and wire	10.50
Clearing right of way and road	52.50

\$646.94

The line was transposed three times in the eight

miles, for which 36-ft. poles were used. We employed a gang of five men, a water boy, and foreman. The men were paid \$5 per day for 10 hours, water boy \$3, and foreman \$7.50. Cutting and delivery of poles and distribution of material was by contract. The men rendered good service, probably 25% better than could usually be had under similar conditions. The engineering expenses were higher than any other part of the work, but under the conditions this could not be avoided. Freight and other small expenses ran the cost up very close to \$750 per mile net, and \$1000 is the least any company should figure on, as poles are more liable to cost \$5 each than \$2, which was the price paid in this case. Local conditions must always be taken into consideration as to cost of construction. Freight to all northern inland points will be about \$75 per ton on this class of material.

D. P. CAMERON.

San Francisco, December 28.

Drill-Steel.

The Editor:

Sir—I have received several letters asking for further particulars about the 'Spiral Drill Steel' suggested by myself in the MINING AND SCIENTIFIC PRESS of December 5. The exact amount of twist that the steel will stand must be determined by test. It is my opinion that a quarter turn to an 8-ft. drill will be sufficient to keep the hole clear of cuttings in all except the softest of rocks, where more turn would perhaps be desirable. The twist, or turn, is so magnified in the backward stroke of the piston by its rotation that each rib will offer a continuous lug for the full length of the drill-stock. Then too, when the drill is running in a 'free' hole, that is, not binding in the hole, the piston does not entirely stop rotating at the end of the backward stroke, but is still turning as it starts on its forward stroke; thus the twist of the steel is likely to become a minus quantity. I am informed by R. A. Kinzie that a test of the steel is to be made at the Treadwell mine as soon as circumstances will permit, and no doubt a report of the test will appear in this paper in due time. As to the effect this twist will have on the strength of the steel, I would be pleased to hear from others. This is a vital point, and the only one on which I have any doubts.

K. NOBLETT.

Treadwell, Alaska, December 20.

The Disaster in Italy.

The Editor:

Sir—Though offering no scientific explanation of the cause of the late catastrophe, I would suggest that an editorial on the effect of it upon world politics, would be welcome. We have had the dread of war for several years, which would ultimately involve the entire civilized part of the inhabited areas. First came the earthquake in this, our home town, and we felt immediately the throb of sympathy from humanity. Then followed Valparaiso and Kingston to knit more closely the bonds between the various types of reasoning animals, all of whom carried red blood in their veins. Lately the rumors of war and the changes in the map of the inhabited

portions of the globe have become more virulent (if I may use the term), and now how does the world feel? Every nation is vying with the other in rendering aid to our stricken brothers; Russian and Japanese, German and French, American and Spanish are extending the hand of charity to our fellows, now suffering the worst that Dante ever pictured in his native land of Italy. It is a thought that has come to me, a pupil in scientific knowledge, that no matter how we may explain the material phenomena, the final result will be to increase the mutual respect of all nations for each other, reduce the friction that produces war, and makes us all akin, one nation, one people. To give and to take without the agency of the cannon and the battleship, and be able after a wordy discourse (from which each derives benefit) to shake hands, and generally to understand and believe the old adage that a soft answer turneth away wrath, as well as that there are always two sides to a question.

Such a disaster as has just occurred will do more to knit all of us together than any war with its subsequent resentment, any peace-meeting at the Hague, where each nation still tries to dominate, or any triumph of science in overcoming the forces of nature. I trust we can read something of moment from your pen should you consider the above suggestion of any value to the public, leaving the scientific discussion to the time when we have facts.

W. J. ADAMS.

San Francisco, January 2.

Ely, Nevada.

The Editor:

Sir—In your issue of January 2, in an article written by Courtenay De Kalb on 'Copper Mining at Ely, Nevada,' it is stated that "The name of Ely was not transferred from Ely, Vermont, to Nevada." I wish to make a correction in the history of the now famous copper city and in memory of Smith Ely. I can do so with assurance, as the place was named by myself. Thomas H. Selby, nephew of the founder of the Selby smelting works, and myself were partners, by purchase or location, in nearly all the copper claims in the Robinson district, Nevada, more than 30 years ago. We disposed of a half interest for \$35,000 to Smith Ely, of Ely, Vermont, through his copper expert, Joseph Long. We purchased a ranch on Murray creek, containing some 320 acres; patent issued to George Lamb, but was claimed by a Mr. Cummins, to whom the judges of White Pine and Eureka counties, with a third arbitrator, assigned the title on the ground of fraud. This ranch covered the site of Ely, where the first copper smelter was erected. As we needed a postoffice at once it was necessary to name the place. Mr. Selby, Joseph Long, Lewis Williams, afterward for 20 years metallurgist at the Copper Queen in Arizona, and myself held a consultation in our cabin over a name for the new place and post-office. None of us cared to be immortalized in this connection, and so I suggested the name of Ely, as a compliment to Smith Ely. We all thought it was just the proper name and that it would please Mr. Ely, as it did. I obtained the first postoffice, with

the privilege of a daily mail. For many years I lived near Steptoe valley, having been connected with various mines in the vicinity. I was well acquainted with the Mr. Ely of whom Mr. De Kalb speaks. He had nothing to do with the naming of Ely in White Pine county, but his name survives in the Raymond & Ely mine and the Ely district some hundred miles or more distant, in the neighborhood of Pioche, Lincoln county. Williams and Long are dead. Thomas H. Selby is living in Mexico, and can corroborate what I have said.

F. F. THOMAS.

Berkeley, January 4.

The Editor:

Sir—I am glad to have the correction communicated by Mr. Thomas. It is in a certain sense significant of the creative energy, still a dominant characteristic of the West, that it is so absorbed in the work of developing natural resources as to lightly treasure its historic records. Earnest efforts were made to ascertain the very facts which Mr. Thomas now supplies, and as a result of correspondence with those long identified with the district the discordant opinions collected at Ely were reduced to what seemed to be the truth. It is interesting to note that a link does exist between the little Vermont mine and the great property in Nevada that promises to be famous as a gigantic producer of copper for generations.

COURTENAY DE KALB.

San Francisco, January 6.

Loss of Cyanide.

The Editor:

Sir—In your issue of November 7, Rivers R. Baildon asks for "some information regarding the mechanical loss of cyanide incurred in operating such slime-filters as the Moore, Butters, Kelley, or Burt." The loss due to chemical decomposition is difficult to determine; but cyanide consumption is due to chemical loss and to mechanical loss. Each ore treated by cyanidation causes an unavoidable chemical loss of cyanide, which is constant for any given set of conditions. The factors determining the chemical loss vary with the character of the ore, the loss increases with fine grinding, increases with strength of solution used, depends upon the degree of alkalinity of solutions, and upon the amount of solutions used per ton of ore.

Mechanical losses are due to leakages, and to loss of cyanide in the discharged residue. The following is an account of losses in the North Star mill, at Kofa, Arizona: The ore is a hard, compact, silicious rock, carrying much free gold. Losses from leakage are slight. Losses in residues from the Kelley filter-press vary from 0.04 to 0.7 lb. per ton of residue discharged, the amount being directly proportional to the cyanide strength of the wash solution, and to a lesser degree to the length of time of wash, and rate of wash. The ore, after coming from dry-crushing rolls and passing through a No. 16 mesh screen, is fed to an Abbé silex-lined tube-mill, and ground to slime, in a cyanide solution containing about 4 lb. potassium cyanide and from 2 to 4 lb. lime per ton.

The ground slime receives an air-agitation in cone-bottomed vats, after which it goes to the Kelley press.

An actual example of the working of the press and of the mechanical losses follows, the filter-press charge consisting of 1066 lb.:

	Minutes.
Time filling press with pulp, sp. gr. 1.27.....	4
Time loading frames	12
Discharging pulp and re-filling with solution.....	5
Solution wash	10
Discharging solution-wash and re-filling with water-wash	4
Water-wash	10
Discharging water-wash	2
Discharging cakes and returning frames.....	21

Total time of cycle.....1 hr. 8

The cake formed contained 28.4% moisture, was 1¼ in. thick, and there were 410 sq. ft. of filtering area. The cyanide in the original pulp was 4.7 lb. per ton of solution, and the cyanide in the wash-solution was 3.8 lb. per ton.

The water-wash began at 0.4 lb. KCy per ton and ended at 0.2 lb. per ton, due to the addition of fresh water during washing. The actual mechanical loss in this case was 0.0568 lb. KCy per ton of dry slime. No cyanide-solution is intentionally run to waste in this plant. For this reason, the wash-water is sometimes dispensed with to prevent an accumulation of mill-solutions. Had a 20-min. solution-wash been given, instead of the solution-wash followed by the water-wash, the mechanical loss of cyanide would have been 1.07 lb. per ton of dry slime. The actual total cyanide consumption over a period of three months, calculated from tonnage of ore treated and the potassium cyanide used, was 2.23 lb. per ton of dry slime.

The cyanide loss, per ton of dry slime, at the Butters Devisadero mines, in Salvador, Central America, in the summer of 1906, was 3.38 lb. KCy per ton of dry slime. This plant was then all-sliming. The ore was slimed in cyanide solution in a tube-mill having a cast-iron lining; the fine iron worn from the lining was accountable for the high cyanide consumption. A test made when the pulp carried 0.12% KCy per ton of solution, with wash-solution at 0.058% and wash-water free from cyanide gave at the end of a 45-min. solution-wash 0.069% KCy in the discharged solution, and at the end of a 30-min. water-wash 0.039% KCy in the discharged solution. The moisture in a cake from the Butters filter runs from 28 to 40%. The mechanical loss of cyanide is from 0.21 to 0.55 lb. KCy per ton of dry pulp.* Cyanide solution was never intentionally run to waste.

DANA G. PUTNAM.

Kofa, Arizona, December 18.

The gold output of Rhodesia for September, of this year, was 48,573 oz., of which 26,540 came from Matabeleland, and 22,033 from Mashonaland. Since the commencement of mining operations in that colony the gold production has amounted to 3,061,582 oz., having a value of £11,211,920.

*The Filtration of Slime by the Butters Method.' E. M. Hamilton, MINING AND SCIENTIFIC PRESS, JUNE 29, 1907.

METAL PRODUCTION IN 1908.

The United States Geological Survey issues the following statistical review:

Copper.—To the copper industry of the United States the year 1908 was a period of gradual recovery from the severe depression suffered in the last part of 1907. Many producers that had greatly curtailed or even suspended production in that year began again to increase their output at the opening of 1908, and in spite of the low price of the metal, nearly all the important producers were in operation throughout most of 1908, and a few new companies began production during the year. The rate of production has been steadily increasing, and is now greater than at any other time in the history of the industry. The production of copper in 1908 has been ascertained by L. C. Graton, of the Geological Survey, through personal interviews and telegraphic communication during the last days of the year. Except one small company, all producers of blister and Lake copper have furnished their latest exact figures, in most cases for eleven months, together with estimates of their production for the remainder of the year. If these estimates are realized, the production of blister and Lake copper in 1908 from ores mined in the United States will be greater by about 50,000,000 lb., or between 5 and 6%, than that in 1907, which was 868,996,491 lb. It is impossible at this time to publish figures of State production, but it may be said concerning the three great copper producing States, that Arizona and Montana show large gains, while Michigan shows little change from 1907. Production of total refined new copper by works in this country hardly equals the output of 1907, which was 1,032,516,247 lb. Based on records of the Bureau of Statistics covering the first 11 months, the 1908 imports of copper in pigs, bars, etc., are estimated at about 160,000,000 lb., and in ore and matte at about 53,000,000 lb. With addition for copper in pyrite, not included above, the total imports may be estimated as equivalent to about 210,000,000 lb. refined copper, a decrease of about 13% from 238,031,320 lb. in 1907. On a similar basis, the exports of metallic copper are estimated at about 660,000,000 lb., the largest ever recorded, and an increase of about 30% over the 508,929,401 lb. exported in 1907. Stocks of refined copper are still undoubtedly large. Domestic consumption of new copper will show a decline from the 485,000,000 lb. of 1907. The average quoted price of electrolytic copper at New York for 1908 was 13.20 cents. The price at the close of the year was 14.18. The prospect is bright at the present for a still larger copper production in the year 1909.

Spelter.—The production of primary spelter from domestic and foreign ores in 1908 is estimated at 208,000 short tons, worth at the average price \$19,656,000, as compared to 249,860 tons in 1907, 224,770 tons in 1906, and 203,849 tons in 1905. Imports of zinc ore comprised 26,000 tons of duty-free calamine (silicate ore), valued at \$22,000, and 34,000 tons of dutiable ore (carbonate and sulphide), valued at \$383,000. These imports, which were practically all from Mexico, show a decrease of nearly 50% over

the quantities of the corresponding ores imported in 1907, which were 81,973 tons, and 28,867 tons respectively. The exports of zinc ore also show an increase, being 26,108 tons, worth \$877,745, compared to 20,352 tons in 1907. The imports of spelter show a decrease of 50%, being 894 tons worth \$85,000, compared to 1778 tons in 1907. The exports of spelter show a marked increase, being 2500 tons, valued at \$238,000, as against 563 tons in 1907. The exports of zinc dross were 8683 tons, in value \$483,000, compared to 9593 tons in 1907. Prices maintained a uniform but very gradual ascent throughout the year. The average New York price of prime Western spelter for the year was 4.73 cents per pound, the extreme fluctuation in value ranging from 4.32 to 5.15. The production of spelter from domestic and foreign ores, apportioned according to States in which smelted, was approximately as follows: Illinois, 49,500 tons in 1908, as compared to 56,056 tons in 1907; Kansas, 98,000 tons in 1908 and 134,108 in 1907; Missouri, 10,000 tons in 1908 with 11,732 in 1907; Oklahoma, 15,000 tons in 1908 against 5035 tons in 1907; Western, Eastern, and Southern States, 35,500 tons in 1908 and 42,929 tons in 1907. These figures of production, prepared by C. E. Siebenthal, of the Geological Survey, are based on reports received from all operating zinc smelters.

Lead.—The total production of primary refined lead, desilverized and soft, from domestic and foreign ores in 1908 was approximately 391,000 short tons, worth at the average price \$32,844,000, as compared to a production of 414,189 tons in 1907 and 404,699 tons in 1906. These figures are exclusive of an estimated output of 12,000 tons of antimonial lead, as against 9910 tons in 1907. Of the total production, desilverized lead comprised 287,500 tons, as against 314,241 tons in 1907. The soft lead production increased to 103,500 tons, compared to 99,948 tons in 1907. The increased output of soft lead accompanying a decrease in desilverized lead means apparently that Missouri retains the first place among lead-producing States. There was 50% increase in the imports of lead in ore and base bullion, which amounted to 105,000 tons, valued at \$4,160,000, as compared to 70,538 tons in 1907. From this it may be inferred that the production of desilverized lead of foreign origin increased considerably over that of 1907, which was 67,423 tons. The imports of refined lead fell off considerably, being 3000 tons, with a value of \$200,000, against 9277 tons in 1907. The exports of foreign lead (lead of foreign origin smelted or refined in the United States) show a similar increase of nearly 50%, being 75,000 tons, valued at \$3,024,000, compared to 51,424 tons in 1907. The exports of lead manufactures remained practically stationary, with a value of about \$600,000. The price of lead started in January with a minimum of 3.625 cents per pound, rising to the maximum figure of 4.60c. in August, then declining slowly to the close of the year. The average New York price for the year was 4.2. These figures of production were prepared by C. E. Siebenthal, of the Geological Survey, from reports and estimates by the desilverizers and the soft-lead smelters.

THE YUKON DITCH.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

In order to facilitate the exploitation of gravel deposits situated on the Klondike river and its tributary creeks, the engineers of the Yukon Gold Co. have built a system of ditch, pipe, and flume that has a total length of a little more than 70 miles. In July, 1908, it was my good fortune to observe the building of this conduit and to note some of the details of an engineering project as important as it is costly.

The country traversed by this ditch is a rolling woodland indented by the alluvial flats of the Klondike, the Twelve-Mile, and other streams flowing into the Yukon river. As seen from a height the wilderness stretches unbroken from the meandering shimmer of the Klondike, enclosed within high banks on which white scars mark bench-diggings, to the Ogilvie range, where, far to the north, the snow still lingers in token of the gift of water that shall enable man to win the gold from the deposits of gravel strewn the tortuous valleys. The engineer who first planned the line of flume, ditch, and pipe had imagination—that kind of constructive imagination which is the creative force behind all engineering work. He imagined the deed done, and then he calmly began to calculate how to accomplish it. As viewed from afar the panorama of wooded valleys, and the distant range that serves as a watershed, afford no suggestion of the natural obstacles to be overcome, but a closer acquaintance soon demonstrates that the forest is but a scant growth of small trees, just fit for telephone poles, not big enough to yield lumber, struggling to assert a stunted life amid the vast morass covering the face of the land. A soggy blanket of moss mantles the ground, which is held in the grasp of a perpetual frost. Under the moss is ice; the moss forms an insulating blanket so that even the short warm summer does not thaw the frozen ground lying beneath this dark green coverlet. In places the ice melts slightly and pools of water form. Everywhere the surface is wet and sloppy. Our horses splashed through it. We stumbled over the spongy mass. It is a dismal swamp, which becomes almost impassable when torn by traffic. Wherever a trail was worn by use, it became a quagmire and it was best to turn our horses to the untrodden moss alongside; in this their feet would sink to a depth of 6 or 8 inches, for below that was the frozen ground; while in places, where the moss was cut and worn away, the thaw had reached deep enough to make progress impossible. And these conditions obtained not only on the flats, but on the slopes. The water is held by the moss as by a sponge, so that even over an undulating topography there were no running streams.

Roads of the corduroy type have been constructed, moss being laid on the poles and dirt on the moss. The trails traverse the brush in straight lines. Horses and men, steam and muscle, have fought against the wilderness and subdued it. The big ditch looks like a Panama canal and the steam-shovels groaning and

digging in the deep cuts recall pictures of Culebra. Many of the laborers had worked on the isthmian canal, and assuredly the young engineers were as proud of the work they were accomplishing as if it were a national or even an international enterprise. The wilderness that had laid in shivering silence for untold ages, responsive only to the footfall of the moose and the cariboo, hearing only the voice of the stream and crash of the tempest, has been invaded to the very threshold of the Arctic by insistent man, determined to use Nature to his purpose, to overcome her obstacles by turning her own energy and her own power to his good in the quest for gold.

Several schemes for bringing water under pressure

The Tombstone River at the Intake.

to the placer mines on Bonanza and Hunker creeks have been considered during the last five years. One of these involved the use of the water flowing in the Klondike river, but it was ascertained by survey that the low gradient of that stream would necessitate a ditch fully 85 miles long and an expenditure of about \$7,000,000. A. N. C. Treadgold, the promoter of the enterprise now known as the Yukon Gold Co., made surveys along the tributary streams flowing into the Klondike and the Yukon from the north. Finally he applied for a right of way for a ditch to tap the head of the Twelve Mile river. This enters the Yukon 18 miles below Dawson, and has its source in the Tombstone range, a part of the Ogilvie mountains, which rise to an altitude of 7000 ft., and gather sufficient snow to furnish a constant supply of water. It was estimated that a ditch to the mines near Dawson, with a capacity of 125 cubic feet per second, under a head ranging from 850 to 350 ft., would be 70 miles

long and would cost \$3,000,000. It has cost over this amount to date and will require a further expenditure to complete. The total distance between the head of the ditch and Gold hill, the point of distribution, is 70.2 miles, the difference in elevation between these points being 1112.8 ft. The effective head along Bonanza creek, in the vicinity of Gold hill, is 375 ft. The construction includes 19.6 miles of flume, 38 miles of ditch, and 12.6 miles of pipe. Owing to the nature of the ground traversed, it has been necessary to modify the size and gradient of the ditch according to local conditions, but the standard is a 9-ft. bottom, with 3½-ft. depth of water, and a gradient of 6 ft. per mile, ranging from a minimum of 4 ft. to a maximum of 7 ft. per mile. In places the ditch is fully 20 ft. wide. The standard flume is 6 ft. wide and 4 ft. deep, with a gradient of 0.2841% or 14 ft. per mile. The pipe varies according to the engineering requirements and is variously built of steel and wooden staves, so as to have a diameter ranging from 42 to 54 inches. The accompanying map shows the course of the water system and the distribution of the various forms of construction.

Wherever practicable the water is conducted by ditch, for that is the cheapest and most durable conduit. A ditch is necessarily dependent upon the contour of the surface; where depressions exist, a long detour is saved by building either a flume or pipe. If the depression is a deep ravine or a broad valley, it becomes impossible to construct a flume, and recourse is had to a pipe in U-form (forming a so-called inverted siphon), the loss of effective head being measured by the friction between the water and the sides of the pipe.

In constructing the flume, the sills of the bents are laid in good ground, that is, below the surface dirt, upon solid rock or else upon debris that will not shift after thawing. In laying pipe along a declivity, the weight at the depression is taken by bents carried through the surface dirt to the gravel underneath.

The completion of this ditch in

three seasons, equivalent to one full year of 12 months, is a feat highly creditable to the engineers. in friendly competition; nor did the night crew complain of any handicap through poorer light. At that

season the night is only two hours long, for Dawson is at latitude 64° north.

Electric transmission is effected over 36 miles of main line and 18 miles of branch high-tension line, with 8 miles of secondary lines from 4 sub-stations. The power-plant receives 60 cu. ft. of water per second under an effective head of 650 ft., the delivery from the flume being effected by a steel pipe gradating from 36 to 34 and then to 32 in. diameter. Two Pelton wheels, actuated by a 4-in. and a 3-in. nozzle, respectively, are harnessed to two Westinghouse generators of 625 kw. each. By a three-phase system 2200 volts are

stepped up to 33,000 volts, at which tension the current is transmitted over a No. 5 copper wire. A de-

Where Shovel No. 3 Encountered 'Frost'.

Owing to the large amount of money paid for mining claims, and to the heavy investment of capital involved in the building of the ditch, it was imperative that the water be brought to profitable use as speedily as possible. The first thing was to obtain power for the dredges. A sawmill was built on the right bank of the main Twelve-Mile on a site commanding the best supply of logs. This sawmill was operated by steam-power. Then a flume 5½ miles long, 3 by 4 ft., was built on the stream known as the Little Twelve-Mile, and an electric power-plant was erected near the place where the main water-system would cross the valley and two miles above the sawmill. Meanwhile the survey for a transmission line was hastened. This was in June, 1906, and it is interesting to relate that in

Construction of Cribbing.

Cribbed Ditch.

flecting-nozzle governor is an interesting feature of the Pelton wheels.

While preparations were thus being made for the transmission of power, the work on the ditch was begun. As soon as the surveys were completed, the right-of-way was cleared. The small growth of forest was removed, and the moss stripped from the frozen ground for a width of one chain (22 yards). Then steam-shovels were put to work, and while they were digging the ditch, the sawmill on the Twelve-Mile yielded the lumber needed for the construction of the flume and for other purposes. Seven million feet (board measure) of lumber was cut; this depleted the small forest available, but it proved sufficient.

making the survey for the pole-line the engineers worked both by day and night, the two shifts being Electric power was employed in pulling the lumber up a tramway built from the sawmill to the site of

the flume, this form of construction being confined largely to the first part of the conduit.

Without the steam-shovel it would have been hardly possible to dig the ditch in an economical manner, for manual labor at \$4 per day, plus board at \$2, or a total of \$6 per day, is a costly instrument of engineering. Six shovels were employed. These make the cut, which is then beveled by hand, to be followed by the laying of moss on the sloping sides, with a little fine dirt as a finishing touch.

On July 19 I saw the No. 1 Shovel at work on the Klondike Face. This shovel had then dug 8 miles of ditch. The machine was the Little Giant Shovel, made by the Vulcan Iron Works, of Toledo, Ohio. It weighs 36 tons and uses 45 hp. A 4-ft. extension on both the boom and dipper-handle affords 18 ft. of clearance from the centre of the track. The dipper is re-inforced for this special work, and excavates 1¼ cubic yards at each swing. The machine is mounted on railroad trucks that run on a track of standard gauge. After 5 minutes of digging, the shovel is advanced, the move being accomplished in 5 to 10 minutes. The shovel was digging in soft silt requiring special treatment. Boughs of spruce were laid criss-cross upon the bottom of the cut so as to form a mattress, upon which the ties were laid, and on them the rails. The shovel dug an average of 300 ft. of ditch (9 ft. wide at the bottom) in 24 hours and had made as much as 365 ft. in a shift, the average being 1200 cu. yd. per day, and the maximum 1600 yd. per shift of 10 hours. The fuel used in the boiler was small birch that had been dried in a forest fire.

On July 21 I saw No. 3 Shovel at work on the Bal-larat Division. This machine is a Model No. 20, made by the Marion Steam Shovel Co., of Marion, Ohio; it was making from 35 to 40 ft. in two shifts, but it had made a record of 680 ft. in one shift. The crew in-cluded three men on the shovel, namely, the fireman, craneman, and engineer. In the cut there were 6 men and a boss, all of whom joined forces when the time came to move forward. Two men attend to the lift-ing-jacks and one to the blocks in the rear. The total cost of labor was \$175 to \$200 for the two shifts, this including a roustabout, who gathered wood, and the hauling of water for the boiler. The shovel was do-ing nicely in ground well adapted to a tight ditch. Progress averaged 200 ft. of ditch per shift, each foot of advance being equal, approximately, to 3½ cubic yards. On the low side of the ditch the cut was 5 ft. deep.

Shovel No. 5 was working on the Twelve-Mile Face. This machine was made by the Thew Automatic Shovel Co., of Lorain, Ohio. The State of Ohio is rich in the manufacturers of good machinery. The Thew shovel weighs 35 tons, it has a dipper of 1½ cu. yd. capacity, and a clearance of 23 ft. Owing to the ample swing, the shovel was digging a ditch 20 ft. wide at the bottom. The boom is made fast to the car-body, carrying the engine and boiler, so that the whole machine acts as a unit. It is swung on a four-wheel truck having an 8-ft. wheel-base. The shovel is not suited to soft ground, but does excellent work when digging a shallow wide ditch in moderately hard ground. The machine had made 75 ft. of ad-

vance during the forenoon of my visit and was aver-aging 200 ft. per day of 24 hours.

As the map shows, the aqueduct is separated into divisions each having a name by which it is known to the engineers. A record of progress made on each division is kept by plotting the weekly advance in percentage of the total construction.

Details of construction along successive portions of the undertaking are given herewith, as gathered on the spot, by courtesy of Messrs. O. B. Perry and Chester A. Thomas, the managers.

Tombstone Creek.

41,000 ft. of 4 by 6 ft. flume.
Main intake at 3317.8 ft.

Little Twelve-Mile.

Intake of pipe at 3199 ft.
Discharge into flume at 3104 ft.
Lowest point at 2459 ft.

Details of Pipe.

3,540	Steel	46
429	Wood	49

Slate Creek.

32,000 ft. of 4 by 6 ft. flume.
Less 800 ft. of ditch.
Grade, 14 ft. per mile for flume, or 0.2841%.

On the Twelve-Mile Face there is about two miles of ditch in bad ground. To protect the lower bank 6000 ft. of cribbing was necessary. The grade is 4 ft. per mile. In the Nome region, where ditch construc-tion has been more vigorous than elsewhere in Alaska or in the Yukon country, and where frozen ground obtains, some of the ditches have a grade of 3 ft. only. In a flat country such as that of the Seward Penin-sula the upper bank of the ditch is not made steep and it is found best to use a ditch of wide cross-sec-tion, say 30 to 50 ft. in places. The ditch is cut to 30 ft., and becomes worn to 50 ft. As the frozen dirt thaws in concave form the moss droops over it. If the bank is not too steep nor too high the moss will hold together and eventually blanket the bank so as to hold the frost. The worst ground is that in which not only layers of ice but nearly vertical veins of ice extend through the moss and muck, so as to afford a channel for seepage as the ice thaws. These per-mit the water from the ditch to escape, and it will appear a hundred feet or more from the hillslope in the form of a geyser.

(To Be Continued.)

Next year, when the Bradley patents expire, the manufacture of aluminum, which has until now been in the hands of the Mellons of Pittsburg, will be open to the public. Many deposits of aluminum ore (baux-ite) in this country have been waiting to be worked, and the chances are that the industry will take enor-mous strides within the next few years. The patents expired last year in Europe, and the metal is selling at about 13c. per pound, and the duty into the United States is 8c. per pound. Here aluminum has sold at about twice the price of copper, and is now about 23c. per pound, so the price should be halved in future.

PROTECTION OF INVESTORS.

The discussion held by the Pacific Coast division of the Mining & Metallurgical Society on November 21, 1908, was published in part in our last issue. It is here continued. The trend of the discussion was mainly toward ascertaining what information was due to the shareholders and how it could best be given in the reports issued by the management.

T. A. Rickard.—If you give tonnage without giving the yield per ton, you give no idea as to the value. In other words, you should not alone go through the motions of giving information, but you should give information in the way that you would give it to your own partner.

George W. Starr.—Suppose a mine is producing very well, and that ore is taken from certain parts of the mine; the manager is nursing certain parts of his mine and the investor does not know it. He gives his report out and states that he has got 500,000 tons of ore. If you don't give the value of that tonnage, it is misleading to the investors; perhaps a great many tons of ore are actually worthless.

Charles Butters.—At our mine at San Sebastian, in Salvador, the manager furnishes the secretary with a plan, and on that plan the mine is blocked out in small sections, and on every block is marked the number of tons and the value of the tons in that block. In the report he adds those blocks together and averages all the tons. A man who gets our report would find from it that we had so many tons of ore of a certain value; that would be the only figure given. If he wished to refer back to the little plan furnished with it, he would find out how the total was determined. The detail is all there, and that detail is made up from assays. We followed this system for about five or six years in this mine, in which the ore is high-grade. We found that the number of ounces of gold that we had estimated would always average as anticipated. As a rule our approximate grade has been lower than the blocks showed, but we got more tons.

T. A. Rickard.—Of a lower grade?

Charles Butters.—Of a lower grade than we had estimated: Yes. The number of ounces of gold that we estimated was nearly always correct.

T. A. Rickard.—Give us your views. What information do you think should be given to the shareholders?

Charles Butters.—My idea is that the manager should make himself responsible for every block of ore in the mine. He must have determined the facts from his assays, and the stockholder ought to be able to look back over the reports and maps and be able to find the information he wants. That information should be so specific that if the investor wished, he could review the operations for a series of years. From our plan we could find out that the estimate of the manager at San Sebastian had come out pretty fairly.

T. A. Rickard.—How soon should it be given? It might be a *post mortem*.

Charles Butters.—It is given just as soon as may be, at the end of the year. We give it annually be-

cause we only make an annual report, and we only make up our tonnage once a year.

T. A. Rickard.—Then it wouldn't help the shareholder from a stock market point of view?

Charles Butters.—We never sell our shares.

Mark B. Kerr.—What should be considered ore 'in sight'? For instance, you are running a drift through an orebody, and you have ore in the face, and in a raise. The upper level may not be in so far as the lower level, yet you may have every reason to believe that ore will be cut there also. Of course, if you have a winze ahead of you from an upper level, the chances are that you could draw the lines straight through and give an approximate tonnage. That certainly would come under another clause; that would be 'partly developed ore,' but here in California, at least from my experience, they do not like to give detailed reports as to reserves, especially on the Mother Lode. There the costs are down pretty low, lower than almost anywhere else in the world. You cannot get the details of that cost. As a rule they are not published.

T. A. Rickard.—How much do you think should be told to the shareholders?

Mark B. Kerr.—That is another point. I agree with Bradley on that point. Everything that a manager considers important should be published. As a rule the report of a manager is edited too much, that is, he gives a detailed report, and in that report are certain items that it might benefit the shareholder to know. If the manager can report partly developed ore—possibilities—that would give a better general idea of the value of the mine than just simply putting in ore that is actually exposed on four sides. I think that estimates of partly developed ore and of possibilities should be given to the shareholders.

T. A. Rickard.—To what extent is it practical to do that?

Mark B. Kerr.—I think it is practical to publish the greater part of the information. They can state the ore in reserve and the value of that ore, and the partly developed ore and its value.

T. A. Rickard.—To what extent do the president and directors of companies here consult you with reference to giving such information to investors?

Mark B. Kerr.—They don't want that published. The principal objection is to the publication of working costs. Two or three years ago I was discussing with the directors of a mine on the Mother Lode; they said to me that they would prefer not to have the cost mentioned because if the men in the mine had an idea that this ore was being mined so cheaply, and that possibilities were so good, it might create trouble: they would assume that the company was able to pay them more wages. It might lead to a strike. So the management did not like to publish the amount of ore in reserve or the costs of operation.

J. N. Nevius.—Is it not a question of affecting the stock?

Mark B. Kerr.—In the case mentioned the reason given was sincere. The mine was not quoted on the market. The decision was based upon the labor conditions, without question.

J. N. Nevius.—I had this in mind: We all, of

course, have observed that the value of the stock of a mine quoted either on the listed exchanges or on the curb, does not reflect the intrinsic value of the mine. The price does not rise and fall necessarily with the change in the condition of the mine as represented by the ore-values and probable life of the mine. Such a report as we are discussing—a carefully prepared estimate of the actual condition of the mine—would affect the value of that stock. It would steady the market value of the stock by enabling the public to buy and sell on an intelligent basis, instead of on the strength of rumors advanced by those interested only in manipulating the stock. It would tend to prevent such manipulation and to give to mining stocks a negotiable value they do not possess at present. I assume that it is the sense of this meeting to neglect the stock-values and to give consideration to the technical part of mining, and it seems to me that the manager and board of directors of a mining company bear to a certain extent the same relation periodically to their stockholders as a consulting engineer bears to his client. If any of us as a consulting engineer is operating or directing the operations of a mine, we are obliged to render an estimate of ore reserves and cost-sheets. Now then, from a technical point of view—not the stock point of view—should not a mining company render to its stockholders, for the same reason that the consulting engineer renders to his client, a report showing the exact reserves of a mine and the cost-sheets? I think it should be done once a year.

Charles Butters.—In estimating ore reserves, Mr. Bradley, in a mine, from year to year, don't you find, if you look back over a series of years, that after all it takes a good deal of experience to project an estimate? In other words, in order to make an accurate estimate that a man ought to be acquainted with the mine before his estimate has real value; that a continuous knowledge running over some years in the same mine is important?

F. W. Bradley.—I think that is very true; a stranger to a mine cannot make as good an estimate of the ore reserves and of the probable ore reserves as a man who has been long familiar with the mine and who has worked it several years. A manager who carefully studies his mine by giving the underground work especial attention and who has worked it a number of years should know exactly what the mine is capable of producing. I am, of course, speaking of a producing mine and not of an uncertain prospect. For instance, one way of estimating the ore reserves would be to take the area of his orebody on a specified level; he will know whether that area increases or diminishes on the different levels and he will know what a particular area produces. Another way of estimating ore reserves in a spotty mine where the orebodies are in kidney-shaped masses irregularly scattered throughout a mineral-bearing zone, would be to learn the gait of the mine and its production of tonnage per vertical foot of depth. He can in this way make a close estimate as to what the mine will produce, but in order to do that the mine must have been worked for some considerable time. It would be difficult for an engineer who has

no familiarity with the mine to make as reliable an estimate as the manager who has actually been extracting ore from the mine over a period of time.

Charles Butters.—The reason I asked that is because our Mr. Garthwaite in Salvador has been six or seven years estimating with great care the actual ore in sight and the probable ore in sight, and he has cut out now estimating the probable ore. He prefers now only to give actual ore, after six or seven years' experience.

T. A. Rickard.—I suggest that it is almost impossible to define 'probable ore,' almost as difficult as to define a "reasonable doubt," for instance. It is entirely a matter of the personal equation. One man calls a thing 'probable' ore; another man calls it 'assured' ore; another man, a little bit more timid, or it may be a little more cautious, calls it a 'possibility.' It depends also upon the mine. In one mine 'probable ore' is so reasonably certain as to be called 'ore in reserve.' On the other hand, in a locality such as Georgetown, in Colorado, you can examine a mine that may be making a steady production, and yet you might not find one month's ore in a reserve in that mine, and you might cut up your mine in 50-ft. squares and yet not be able to estimate accurately. All the work in a mine of that kind is done by leasing, and yet in the aggregate, during the year, they get a great deal of ore. Then you would have to fall back upon this scheme that Bradley has mentioned. In that way you can get an approximation. But in the end you will find that a man who is unacquainted with a district like Georgetown is absolutely helpless when examining a mine there.

Charles Butters.—Mr. Bradley, do you ever estimate 'probable ore' for your shareholders?

F. W. Bradley.—I give 'partly developed ore' and 'ore ready for stoping' as ore reserves. 'Ore ready for stoping' would be the manager's estimate as to the actual tonnage he can dig out at a profit and deliver to a mill or reduction plant. A manager could list as 'ore reserves' tonnage of a profitable grade that might have to remain in a mine as pillars. The term 'ore available for stoping' or 'for extraction' would compel him to exclude all pillars or ore necessary to be left as pillars, which cannot eventually be robbed. For instance, I would give as fully developed ore, ore that is ready for stoping. I would give as 'partly developed ore,' ore partly blocked out but not available for stoping. For example, if a shaft were in ore and had been sunk from a level also in ore, there would result a block that I would call 'partly developed ore,' the dimensions of this block being made liberal or conservative according to one's knowledge as to the gait of the mine or as to how the mine had performed.

S. B. Christy.—It seems to me that unless one takes into account and allows for the recognition of partly developed ore, it would kill many good mines in process of development. As Mr. Rickard has pointed out, if you insist on allowing only for developed ore, it would be fatal to many good mines in process of development. In such mines, all that there is is partly developed ore. This difficulty might be met by requiring the manager of a mine to distinguish,

in his report, between developed and partly developed ore, and to hold the manager responsible and criminally liable for misrepresentations in his reports. That is, if he represents to the stockholders that the ore actually developed contains a given tonnage and assay-value, which afterward proves to be a gross exaggeration, he ought to be criminally liable. It seems to me that such a law would clarify the atmosphere very quickly.

T. A. Rickard.—I would like to suggest that there has been a good deal of discussion as to ore in sight, ore in reserve, and the like, and that the term 'ore ready for stoping' describes it better than any other phrase. That means ore that has been cut by drifts and raises. I don't know what the next step would be: Ore that has been 'partly developed'. There, again, you must define what you mean by 'developed'; men differ in their notions. You don't want to use a word that requires definition each time it is used. What you call partly developed another man might not think so. But 'ore ready for stoping' is pretty clear. When you sink a shaft or winze here and drive a level there, you have got practically two sides of a square.

S. B. Christy.—'Partly developed ore', or 'possible ore', or some such term might be used. The reasons for belief in the possibilities of the mine should be clearly stated; that is the point.

T. A. Rickard.—So, then, we start with 'ore ready for stoping'. That will express the idea to anybody. Then the next thing is to describe ore the existence of which is partly proved; let the engineer or manager explain to what extent the existence of that ore is proved.

George W. Starr.—The degree of probability.

T. A. Rickard.—Yes; in one case you may require a great deal of proof and in another very little. On the Rand the sinking of a shaft and the running of a drift would be all the proof that is necessary. In Goldfield you would have to do much more to establish the existence of a body of ore that could be considered assured.

George W. Starr.—In some cases the term 'ore ready for stoping' would be misleading for the reason that, in many mines, a good deal of stoping is done backhanded without any connection, and stoping would be carried on before connection was made. Whereas, if you would call it 'blocked out ore', or 'ore in sight'—

T. A. Rickard.—That is tabooed.

George W. Starr.—We understand what 'ore in sight' means. It is as far as we can see it.

T. A. Rickard.—We don't see it.

George W. Starr.—We have got it assayed and blocked, and it is practically in sight.

S. B. Christy.—Ore exposed on four sides.

George W. Starr.—But 'ore ready for stoping' is misleading.

S. B. Christy.—I think so, too.

T. A. Rickard.—In a mine where, as you say, you begin to stope from the back, the ore is so regular that you can assume that it continues upward.

George W. Starr.—Suppose that you are running your drift, and you start stoping right from the back

of that drift, you will carry a great breast right up through. You will be running that before your drift is connected, and you can carry your ore across.

T. A. Rickard.—We are all evading the question. The question is how to protect investors.

Ernest A. Hersam.—It is important to define the terms we are using.

George W. Starr.—I think that one of the most essential things in valuing your mine is the quantity of ore that there is in that mine that you can figure on, and thus give to the investors the value and the tonnage of ore ready to stope. And I would suggest that we confine ourselves for a while—that is, if it is acceptable to the others—to discussing that question, because I think that is one of the most vital points of a mine, and one of the points that a stockholder should know.

Charles Butters.—I did not quite understand you, Starr.

George W. Starr.—I think one of the most vital points for a stockholder to know is the amount of ore there is in a mine and the value of that ore, so that in discussing this question we should consider the form of report necessary.

T. A. Rickard.—Yes, of course, we agree that that is important, but the practical question is as to when and how the shareholder is to get the information. If the information is given in an annual report, which gives the story of the mine up to the end of December, and the report reaches the shareholder the first of June, he has got a graceful *post mortem*. It won't do him much good.

George W. Starr.—It certainly will if he has ore that will last over that period.

T. A. Rickard.—In some mines, yes; but in most cases he would be more interested in learning what had happened at the time than six months after the report was written, as affecting the value of his interest in the mine.

S. B. Christy.—That is the important point; for if the management had the information promptly, and the stockholders had it six months later, you can see what a chance there would be for speculation. It would be possible for those 'on the inside' to do anything with the stock of that company.

C. C. Derby.—I do not see why such information cannot be furnished the stockholders promptly, at the end of the fiscal year or for such periods as may have been determined. In several cases where I have heard complaint made by stockholders regarding the tardiness of the appearance of their reports, it was not the fault of the manager, as their information had been furnished promptly on the completion of the period to be reported on. At most mines it is possible to have all the data necessary worked up to the end of the last month, so that in a short time thereafter the manager can have his report ready to hand to his home office for distribution to the shareholders. It is then the duty of the main office to transmit the information promptly to those entitled to receive it. As a rule I think those in charge of the main offices are more at fault than the managers in direct charge of operations, for delay in furnishing reports to shareholders. In most instances the

manager can, and should, submit his report in short order. The shareholders in a mine are the owners, and are certainly entitled to all the information regarding their property that may be possessed by their employees, from the president down.

S. B. Christy.—I think it would be better to confine ourselves to our text, and find out, first: What are the general items of information that should be in a report? I think we are all agreed on the fact that the tonnage of ore actually developed and its value, constitute the first essential item. Second, it seems to me that there should be in the report itself sufficient data for any investor to check the calculations, and conclusions of the manager, and see whether or not they are borne out by the facts given. For example, it should be stated how many tons of ore are exposed on at least four sides; then how many tons of ore are exposed on three sides; how many tons on two sides; and how much ore opened up on only one side. The distances at which the samples were taken, the method of sampling, the width of the vein at the points where the samples were taken, in detail or in averages for each block—these facts should be given, together with the dollar-feet, in detail or by averages, for each block of ore exposed. If this were done, and the manager were aware of the fact that each investor had the material for analyzing and criticizing his report, either in person or through the employment of a competent expert, it would do more than anything else to secure the proper and intelligent development of mining properties, and would be also an effective guarantee against fraud.

C. C. Derby.—I think Prof. Christy's definition for 'ore in sight', of 'ore exposed on four sides', is better than Mr. Bradley's term of 'ore ready for stoping': Take, for instance, our cinnabar ore, as it occurs in most of the mines in this State; as soon as ore is struck in a drift and the face can be advanced sufficiently beyond the point of encountering the ore to permit of stoping, stoping is begun. We do not attempt to develop the ore, for the reason that it occurs in such irregular bodies and masses that it is almost impossible to do so. So that the definition for 'ore in sight' of 'ore ready for stoping' would not convey the same meaning as 'ore exposed on four sides', when applied to the usual method of mining cinnabar ore.

S. B. Christy.—In that case it would still be possible to say it is exposed on two sides or on one side.

C. C. Derby.—We would call any ore 'ready for stoping' as soon as we cut it in a drift.

J. N. Nevius.—You couldn't say how many tons.

E. P. Kennedy.—The prime object in working a mine is to produce as large profits as possible, while not neglecting to exhaust the probabilities of finding ore. The dividing up of ore into blocks to accurately estimate its value may, or may not, conform to the most economical method of working the mine. I shall call attention to the fact that we are speaking of a mine and not a prospect, and therefore would consider exposing ore on four sides for the purpose of accurately determining its quantity and value as an unnecessary expense. The history of the mine and an intimate knowledge of the vein, plus two

exposed faces, and sometimes with but one, would, in some cases, give sufficient basis for estimating the value of a block of ground, and often would be a better basis for estimating than the mere sampling of four exposed faces. The accuracy of the estimate obtained from sampling four exposed faces of a block of ore depends largely upon the mode of occurrence of the ore, and the size of the block.

The term 'ore ready for stoping' conveys the idea that the ore is ready to extract, the aim in all development work. We presume a mine is opened up to produce the best economical results, and in so doing the ore may be exposed on four sides, but the fact that the ore is not so exposed implies that this is not the most economical way to develop ore. The tons and value of 'ore ready for stoping' may be based on the assay and widths of samples taken from one or more drifts, together with the knowledge of the vein; or may be based on the assay and widths of samples taken from each of the four exposed faces of a block. The term 'ore ready for stoping' expresses the practical conditions as they exist, in so far as it is within the ability of the manager to estimate.

T. A. Rickard.—You get this contrast: On the Rand the running of a drift or the sinking of a shaft proves the ore, while in another case—the extreme case that I mentioned in Colorado—you might block it out on four sides, and yet you could not estimate it satisfactorily; so that the number of sides on which ore has been proved does not determine the amount of it with finality.

J. N. Nevius.—You assume that there is ore there ready to stope.

S. B. Christy.—It seems to me that the investor should have access to all the information that the superintendent has. For instance, in certain kinds of formations where there is known to be a well defined ore-shoot, we all know that the opening up of a block of ore only on one side may be sufficient to enable a reasonable estimate to be made of the value of the block of ore. Of course, the figures represent probable rather than assured values; but the man investing in the property gradually comes to know that, and he takes his chances on it. The point is that in estimating the value of ore in a mine, all the evidence necessary to form an estimate of the volume of ore and its richness ought to be given.

E. P. Kennedy.—It ought to be the property of the shareholders.

T. A. Rickard.—In other words, the report should be a sincere honest report, and the manager should give the information so that it conveys the maximum of information, just as if I were writing to you, and had to tell you what was in a mine. I would try to convey the information to you in as few words as I could.

S. B. Christy.—What I have in view is not that you should force the manager, necessarily, to expose the ore on all four sides. But if he exposes it only on one or two sides, and then tells you that there are so many tons of ore 'in reserve', you ought to have the information that it is not really exposed fully, in order that you may understand that you are taking

certain chances as to what its value may prove to be in future. It would clearly be a mistake to force every mine to be worked in the same manner; but the investor ought to know the way in which it is actually being worked.

E. P. Kennedy.—I think there would be a lot of unnecessary development work if you had to block it out on four sides.

Mark B. Kerr.—Very often you are running a drift, and you are way ahead in that lower strip, and you know your orebodies are strong. You make a 'stoping raise'—I have used that term many a time—that stope goes up 400 ft. before it connects with the level above, but that is just as much a part of the development of the orebody, and it would be mentioned as 'probable ore' just as much as if it were developed on four sides, and there would be only two sides developed, that is, the raise and the drift.

S. B. Christy.—It has often been said that language has been given us for the purpose of enabling us to hide our thoughts; and it seems to me that many of the reports I have read on mines appear to have been written for the purpose of concealing the real condition of the mine from those asked to invest in it. What we want to get at is some form of statement that will force the manager to give the stockholder such information as will enable him to form an intelligent idea of the value of his investment.

Whitman Symmes.—If we do not try to elaborate too much, I think we can have a standard form for mining reports. There are certain questions that every mining report should answer, and Mr. Bradley's question is certainly one of them. The report should state the amount of ore actually developed in the mine and the amount partly developed. Where ore is partly developed, that is, where it is exposed on less than three sides, I think that the engineer should state his reason for including it in his estimates. It is not necessary for ore to be entirely blocked out before it can be considered as a reserve. For example, I was called upon to estimate the available tonnage in a number of small limestone lenses that were to be used by a cement company. Very little development work had been done and they were exposed only on the surface, but it would have been mere sophistry to have stated that there was not a dependable quantity of limestone already exposed. It was an easy matter to determine the general geology of the district and to decide that the limestone extended to an average depth of at least 100 ft.: upon that basis a definite statement of the amount of limestone exposed in the deposits was made. But the depth assumed, and the reasons for the assumption, were clearly stated in the report; and it would not have been fair to the stockholders to have given them a definite estimate without briefly stating the data and reasons upon which the estimate was based. I do not think that any standard definition can be framed which will in all cases fairly apprise the reader what is meant by 'partly developed ore', but if the mining engineer gives briefly the reasons for his assumptions, then the whole matter is made clear. In many cases, the reasons given

will be that on the levels where the orebody is partly developed the vein and chimney of ore are found to continue with the same strength of formation, and that the ore has the same habit and value. But a standard form of mining report should be so framed that it is impossible to evade noting such points. The failure to give definite figures, and the definite assumptions upon which those figures are based, as to partly developed ore in a mine is one of the commonest causes for personal loss in mining ventures.

S. B. Christy.—It is a well known principle that always governs in the writing of all good scientific treatises that the author should give his facts absolutely distinct from his conclusions, and that the facts should be so clearly and fully stated that any other competent person, looking over his work, should be perfectly able either to verify his conclusions, if correct, or, if they are incorrect, to draw opposite conclusions from the same facts. And this should always be possible in a mining report. The stockholder should not be forced to depend on the mere opinion of the mine manager; he should have the facts stated so completely that he can either judge for himself the value of the mine, from the report, or else have the report reviewed by some competent expert. While most of the stockholders may not be able or willing to go to this trouble, and might be willing to gamble on the opinion of the manager, the very fact that some one stockholder may be able to prick the whole bubble and expose the deception would be a good check on the unscrupulous manager, as he would find ruin and State's prison staring him in the face if he misrepresented the facts.

J. N. Nevius.—I think that is a very important point; in a mine report the facts should be given separately from the conclusions.

T. A. Rickard.—The highest compliment you can pay a description is that it faithfully sets forth the facts. I remember a paper that Arthur F. Wendt wrote in the Transactions of the Institute years ago, and he gave the facts so faithfully that he gave all the evidence necessary to controvert his own conclusions. As a rule the facts that people give are more valuable than their conclusions, if the facts are sufficiently complete to enable the other man to make his own conclusions. That was an excellent paper of Wendt because the conclusions did not take up much space.

Ernest A. Hersam.—The report should contain a concise and definite statement of the manager's opinion, but there are possibilities and contingencies on either side. The probabilities have a definite value, either a positive one, or a minus one; but they get their value from the element of chance. If the stockholders know the circumstances and the conditions, they can then decide for themselves what risks they are willing to take.

S. B. Christy.—But there is another phase of the question which I think should be considered; that is, the possible effect of a true statement of the fact that there was actually, at a given time, no ore 'in reserve' in a mine. The necessity of making such a statement would ordinarily, of itself, raise in ques-

tion the competence of the management; and yet it may occasionally happen that the management of a pockety mine may be honestly forced to make such a statement, though the mine still has a future before it. The publication of such a report might create a panic, and destroy the value of the stock; but even supposing that it did happen, the result would be that the timid investor would sell out, lowering the value of the stock to a nominal figure. This, while unfortunate for the timid investor, may be the best possible thing that could happen for the public in general. It would enable the more far-sighted owners to buy the stock at a low figure and keep up its production. So far as the long life of the mine is concerned, it might be well to get the weak members out, and give those having faith in the future of the mine a chance to control and manage it. It should, however, be a criminal offense to misrepresent the condition of a mine for the purpose of "freezing out the outsiders." The very fact that previous reports of the manager were in the hands of all the stockholders would do a great deal to prevent such swindles. In short, I believe that publicity is the best remedy for corruption and inefficiency in mine management, as well as in other industries. Nothing develops honesty in a man more quickly than the realization that he is held responsible for his actions. It is a well known axiom of good government that power and responsibility must always go together. Nearly all of the corrupting influences of our modern corporation life are due to the fact that the managers and directors of these corporations are able to escape responsibility for their acts. And this growing evil will never be checked until those in power realize that criminal prosecution and punishment will certainly and swiftly follow all abuses of their powers and responsibilities.

Mark B. Kerr.—I would think that any shareholder in a mine, after the facts are given to him, should have the possibilities and the probabilities of the mine also given to him, and then the conclusions after that. Otherwise there would be an advantage for those on the inside who have that information.

E. P. Kennedy.—Men are apt to draw their own conclusions. The manager is in a position to draw the right conclusion.

Mark B. Kerr.—Because after all there is a great deal of chance to be taken in a mine. These ore-bodies are not always straight and easy to mine. Sometimes they pinch out to a mere thread. Then, again, a fault may occur. Of course, all those things, if they are taken into account as probabilities and possibilities, will give a shareholder a fair chance to see what sort of a risk he is taking. The manager should help the shareholders to determine the value of their interest. Then it is a square deal, and if the shareholder gets timid and drops out, he at least has all the possibilities before him, and the directors have not the advantage of inside information.

H. W. Turner.—I think that the point of view of the shareholder has not been brought out clearly in this discussion. In the first place, the manager has the confidence of the shareholders. He is appointed manager because they think he has good judgment,

and can operate the mine economically, and they will accept his general conclusions in nine cases out of ten without investigating the details of the report. Of course, full information about the mine should be given for those investors who want details or who have engineers who can size up the details for them. But I feel pretty certain from my limited experience that the investor depends chiefly on what the manager says. It stands to reason that if the manager is competent his estimate is worth the deductions of all the shareholders put together. They would hardly care to vary much from his opinion. If the shareholders lost confidence in the manager, they would drop him and get another. I think, therefore, that the manager should be particular in his estimate of the developed tonnage in the mine, and its value at the time of his report, recognizing that his general conclusions will be taken by most of the shareholders as reliable, not only as to developed ore, but as to probable ore.

S. B. Christy.—That is, the existing state of affairs?

H. W. Turner.—Yes, and as to probable ore they would also consider him the best judge.

S. B. Christy.—Do you think that the existing system is satisfactory?

H. W. Turner.—You take a report like those of the Bunker Hill & Sullivan; that is very satisfactory.

T. A. Rickard.—We might put it down as the sense of this meeting that we regard it as highly unprofessional for a mining engineer or a mine manager to give a report calculated to mislead the stockholder, even though it be in favor of the Board of Directors. Some expression of opinion should be made.

F. W. Bradley.—We have only discussed the first part of the question. We have only covered the first paragraph.

S. B. Christy.—We consider it the duty of the management of a mining company to furnish the stockholders with the information in their possession, or sufficient information to enable them to have a knowledge of the mine and a knowledge of the average value of the ore exposed in the mine, with the reasons on which the statement of fact is based.

T. A. Rickard.—Yes, except that you have used the word 'management', which is general, and we are concerned more with the individual engineer than with the management.

S. B. Christy.—Well, the circular says 'reports of the management', does it not? It is agreed that the reports of mining companies should contain sufficient information to inform the stockholders as to the amount and value of the ore exposed in the mine, at the time at which the report was written, together with the information upon which these calculations are founded.

Earthquake shocks of violence are usually preceded by fore-shocks over the epicentral region, that is, vertically over the point of greatest strain, according to demonstrations from studies made in Japan by F. Omori.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

WATER-SPRAYING DEVICE FOR PNEUMATIC TOOLS.

—No. 905,387. Albert H. Taylor, Easton, Pennsylvania.

A water spraying device for pneumatic tools, comprising a hollow rotating handle communicating with a water supply, and an ejector carried by the handle, for spraying water onto the desired spot, said ejector having its discharge nozzle in communication with the interior of the handle and its force nozzle in communication with the air supply.

PROCESS OF EXTRACTING ZINC.—No. 905,753. Edward H. Shortman, Bloxwich, England.

The improvement in the art of extracting zinc by distillation which consists in passing the metallic vapors prior to condensation through a lead-intercepting medium consisting of anthracite or hard non-bituminous coal or hard coke in a condition that renders it chemically inert but active by its physical or mechanical properties.

MINER'S SAFETY-CANDLESTICK.—No. 906,449. Frederick Muenger, Hill City, South Dakota.

A miner's candlestick comprising a member provided with a spud at one end, and at match receptacle at the other end, an intermediate candle-holder at one side, a hook opposite the candle-holder, and a scrap-hook adjustably attached to the bottom of said hook, a rod attached to said hook and projecting toward the holder, an extinguisher slidably mounted on said rod, and a spring for moving said extinguisher toward the holder.

ORE-CONCENTRATING TABLE.—No. 906,464. Claude Sherwood, Black Bear, Idaho.

The combination of a concentrating table, a series of separate pockets extending along the discharge side of the table and each having a series of distinct outlets, a series of separate troughs to receive different classes of material from the outlets of the individual pockets, and shiftable means with an opening to register with the respective outlets for directing the different materials entering each pocket through the outlets into separate troughs.

METHOD OF MINING.—No. 904,021. Martin Schwerin, Elizabeth, New Jersey.

The herein-described method of mining consisting in connecting a drift and an open-ended waste-chute by successively slicing on an incline a minable body which is between the drift and chute, and in filling the space formed by the slicing operation whereby the minable material above said space is supported by the filling.

LADLE FOR CARRYING AND TIPPING BLAST-FURNACE SLAG.—No. 906,117. John H. Dewhurst, Sheffield, England.

A slag ladle consisting of two parts divided from each other vertically, means for holding the two parts together and trunnions, the joint between the two parts extending longitudinally of the ladle and in a plane and at right angles to the vertical plane in which the trunnions lie, substantially as described.

CONCENTRATING APPARATUS.—No. 906,205. Wilton E. Darrow, Sutter Creek, California.

A concentrating apparatus comprising a plurality of circumferentially disposed upright supports carrying inwardly projecting arms spaced apart in tiers, each tier carrying a circumferentially disposed inclined ring, a plurality of circumferentially disposed trays flexibly connected with said rings and being adjustably supported by said rotating supports, and pulp supply discharging on said trays.

Special Machinery for Placer Mining.

Written by E. L. BYRON.

Many experiments have been made with different kinds of machinery for placer mining, and since the days of the one man and a pan, many successes have been made with improved devices, so that in this day of advancement, placer ground that a short time ago was considered impossible, is now being worked at a profit.

While it is undoubtedly true that the most common, and up to the present time, perhaps the most successful method of working placers, especially in the Western States, is by bucket-dredges, yet owing to the large cost of the plant, the small operator has been practically shut out from this form of mining enterprise. Again, there are many gravel deposits to which a bucket-dredge is not adapted, especially where the bedrock is uneven. Most of the gold in this class of mining is bound to be found in the crevices in the bedrock, so that the top crust of such bedrock must be removed to get the richest part of the deposit, and owing to the peculiar construction of the elevator-bucket dredges, it is impossible to remove all of the gold that lodges in these crevices.

The accompanying drawing shows a special dredge, with gold-saving machine attachments, designed to fill the requirements stated. All the machinery is mounted on one boat and is compact in every respect; two men are needed

that it can be 'knocked down' and hauled by teams through a mountainous country.

The machinery for this new gold dredge is manufactured by the Vulcan Steam Shovel Co., of Toledo, Ohio. When used as a dredge, the boat is ordinarily built on the ground, and working drawings are furnished by the manufacturers. If, however, timber is not to be had in the immediate vicinity, all material for the boat can be framed at the works of the manufacturer, and shipped with the machinery in a 'knocked down' condition, to be re-assembled on the ground.

Publications Received.

Any of the books noticed in these columns are for sale by or can be procured from the MINING AND SCIENTIFIC PRESS.

MECHANICAL ENGINEERING OF STEAM POWER PLANTS. By Frederic Remsen Hutton. 3d. ed.; 8vo.; 866 pp.; ill.; index. John Wiley & Sons. 1908. Price \$5.

The name of F. R. Hutton is so well known in the field of mechanical engineering, and his book on *Steam Power Plants* has so long been a standard of reference, that interest will be quickened by the announcement that the present edition is in effect a new work. It is not a mere revision; it has been entirely re-written, none of the old plates being retained. The points subject to elaboration in the new edition are chiefly the steam-pipe, and the many auxiliaries which have become so important in the economy of modern

when making an output of from 200 to 1000 cubic yards of ordinary placer ground per day of 10 hours.

This outfit consists of a revolving shovel, that is, a power-shovel mounted on a pivot so that it swings through a complete circle, thus allowing it to dig and dump on all sides. The shovel is mounted on the front end of the boat; it digs the material in front and swings through a half circle, depositing the gravel in the hopper of the gold-saving device mounted on the rear end of the boat.

The gold-saving part of the machine is built to take care of the material as fast as the shovel will dig it. The shovel excavates the material and delivers it into the hopper in the rear. All of the gravel not too coarse passes through the hopper into the revolving screen. This revolving screen has perforations through which the material passes, the gold particles passing into the shelves lined with cocoamatt and the waste out into the sluices and up over the conveyor-belt to the dump. Rippers are provided in the sluice-boxes to recover any gold that may have passed through the matting.

This machine can not only be used in wet placer mining, but all machinery can be easily removed from the boat and mounted on standard trucks or traction-wheels, and operated on dry placers. The change converts the machine into a standard revolving shovel for all classes of dry placer work, and the gold-saving machinery being mounted on trucks or traction-wheels and attached to the rear end of the shovel, makes it practically a duplicate outfit of the dredge machine. This machine is arranged for either steam or electric power. It is also constructed in such a manner

plants; the steam-turbine also receives treatment appropriate to its increasing importance as a factor in power-generation.

COMMERCIAL HANDBOOK OF CANADA. Heaton's Annual, for 1909. Edited by Ernest Heaton and J. Beverley Robinson. 8vo.; 418 pp. Heaton's Agency, Toronto. Price \$1.10.

This contains all that a national reference annual is supposed to cover, and some things besides. For example, the existing tariff schedules and regulations are given in detail, as are also the Provincial regulations affecting foreign corporations; trade-mark, patent, and copyright laws; fishery treaties; boiler regulations, and the like. There is included a mineral directory; and a trade register covering the principal towns of the Dominion. A résumé of the mining laws would have added value to the work.

SMOLEY'S PARALLEL TABLES OF LOGARITHMS AND SQUARES. By Constantine Smoley. 5th ed., revised. 8vo., 130 pp. Engineering News Publishing Co., New York. 1908. Price \$3.50.

The additions to this well known handbook for the structural engineer consist of a multiplication table for rivet-spacing, common logarithms of numbers from 0 to 10,000, with tables of proportionate parts, logarithms of the sine and tangent from 0 to 3°, and of the co-sine and co-tangent from 87 to 90°, varying by 10 seconds, with proportional parts for seconds; logarithms of the sine, co-sine, tangent, and co-tangent for each minute of the quadrant, with proportional parts for seconds; and a table of natural functions. The work is a sort of universal calculator, available for computations in either the English or metric systems.

EDITORIAL.

DIVIDENDS of mining companies operating on the Rand aggregated £8,753,000 in 1908, as compared to £7,131,000 in 1907; this is an increase of about 23 per cent. The most productive mine in this regard was the Robinson, which distributed £825,000, and next came the Simmer & Jack, with £675,000. The list includes 53 companies, of which five appear as dividend-payers for the first time.

OWING to a strike among miners, the Broken Hill Proprietary mine is idle and 4000 men are out of work. Wages were raised when the price of lead advanced and the company wanted to reduce wages when lead went down. The men did not see it that way and struck. Other mines at Broken Hill are not affected, but the Proprietary is an important producer and the lead market ought to be strengthened by the event.

COBALT has done well of late, and even the Nipissing has recovered from the fiasco of two years ago. In four years the silver mines of the Cobalt district have yielded \$20,800,000, and out of this they have paid \$11,627,000 in dividends. That is a splendid record. The ore produced has been small in tonnage but high in value: 47,178 tons, averaging \$440 per ton. During 1908 Cobalt yielded \$9,100,000, despite the drop in silver. In addition to its own productiveness, this mining centre in Ontario has stimulated prospecting over the wide region of Canada stretching from the Great Lakes to Hudson Bay.

SHARES of Oroville dredging are at a discount in London, and there is much disappointment over the unsatisfactory outcome of this Anglo-American enterprise. While the nucleus of the original dredging ground was good, the Bear River tract is considered locally to have been much over-rated. Inferences from drilling have not been confirmed, for that preliminary but essential method of testing dredgeable ground was not as well understood in 1905 as in 1909. We are informed that the best of the area has been worked during the past two years, so that the reserves have been seriously trespassed. The original estimates and reports relating to this undertaking were prepared by those who were promoters of the company; comment is superfluous. It is an old stupid blunder, repeated again and again. Neither the ability nor the good faith of the projectors is questioned, but it cannot be doubted that a serious error of judgment explains why the pound shares are unsaleable at eight shillings. Elsewhere, on the Yuba, the same manager is obtaining magnificent returns, and we regret, for the sake of the reputa-

tion of California in London, that the British are not more largely interested in that enterprise also. At the recent meeting of the Oroville Dredging company, it was announced that an option had been obtained on a large and valuable tract of dredging ground in Colombia, and that it was proposed to use some of the Oroville dredges and some of the Oroville experience in this new enterprise, hoping thereby to redress the balance of disappointment. This seems a good idea, if the shareholders have confidence in the present management; there is no reason why they should be timid in that regard if they are co-partners in the new venture. Incidentally we note that the examination of the Colombian property was made by Mr. C. H. Munro, who is now manager of an important group of alluvial mines at Nome. We are glad to be able to testify that his opinion concerning the prospective value of dredging ground is authoritative, for he is known to us to be both careful and experienced. It is possible, therefore, that Oroville Dredging, Ltd., may be resuscitated, and that an error of judgment may be retrieved.

WE NOTE that Major W. P. Richardson, president of the Alaska Road Commission, has appeared before the military committee of the House of Representatives to urge the voting of funds for the completion of the wagon-road from Valdez to Fairbanks, and for other pioneer work of the same kind. It is a pleasant duty to record our acquaintance with the nature of the work done by the Road Commission of Alaska and to give our unreserved endorsement to the request for Congressional support. The building of wagon-roads does not appeal to the imagination as much as the construction of railways, but in a new country the first is often more useful than the second; the wagon-road is a public highway, open to all; the railway is a licensed line of traffic controlled only too often in the interest of a few; one favors free competition, the other inclines toward monopoly. Alaska needs wagon-roads first, and railways later.

Depreciation of Gold.

Our contemporary at New York publishes a most interesting article on the supposed relation between the depreciation of gold and its cheaper production. The author of the article is Mr. W. R. Ingalls; he is to be congratulated not only on a scholarly discussion of an important subject but on the presentation in a lucid manner of an array of facts calculated to clarify future debates on a matter of prime importance. Mr. Ingalls shows by statistical diagrams that (1) there is no parallelism between the rise in the prices of commodities and the production of gold, (2) the rise in the production of iron has accompanied the increased production of gold, but in greater ratio, because (3) the advance in commerce and industry has exceeded the supply of metal. He easily refutes some of the dicta of supposed economists, and exposes the inaccurate statements of writers unfamiliar with the details of gold mining. Finally, he assigns the rise in commodity

prices to complex causes, among which are exhaustion of natural resources, decreased efficiency of labor, extravagance of living, over-extension of enterprise, and failure of agricultural development to keep pace with the growth of population. Even those who do not accept all his conclusions will find that he has compiled a mass of valuable data, from which they can make their own inferences. It was high time that a few facts were introduced into a discussion that had become nebulous. Thus, another contemporary, also published at New York, discusses 'The Increase of Gold Production and the Increased Cost of Living' only to befog the subject. What illumination is likely to come from a writer who says that "at present, gold production, which was restricted in 1907, is now increasing more rapidly than ever and piling up so fast that the reserves of gold in Paris, New York, London, and Berlin are enormous." A pretty bit of reasoning this! In the first place the gold production of the world in 1908 showed but slight increase by reason of the effect of industrial depression upon the mining of copper, lead, and other metals with which gold is associated in ore deposits; and as to the reserves of gold in the banks indicating a big production of the metal, by the same token the gold production of the world must have risen suddenly and enormously during the recent unpleasantness when the banks deemed it necessary to call in their balances.

A good example of a local depreciation of gold by reason of the ease with which it is extracted from the earth, is afforded by Dawson during the Klondike rush, when the commodities of life were relatively, and momentarily, scarcer than gold 'dust.' Sugar fetched \$1 per pound, flour \$10 per sack of 50 pounds, potatoes 75 cents per pound: a pick was worth half an ounce of gold and a keg of nails could be exchanged for five ounces. Labor was worth \$1 per hour and champagne \$15 per pint. These high prices were due in part to the distance from a source of supply and the great cost of transport, but when men pay 50 cents for one dance and \$15 for a pint of champagne, it may be assumed that money is coming easily. Long before the method of transport was improved or even the supply of commodities much increased, the waning of gold production, following upon the exhaustion of the shallowest and richest diggings, had depressed commodity prices by lessening the amount of gold to be squandered by successful prospectors. Moreover, in such a community of irresponsible adventurers there is at first no credit asked or granted. Everything is paid in cash. The gold 'dust' is taken from the 'poke' and weighed on the scales, in exchange for a pick or a drink, a loaf of bread, or a keg of nails. This is simple barter. At the same time and in the same place, the Indians exchanged fish for tobacco. As the mining camp becomes established, banks are started, mercantile concerns systematize business, and a complex structure of credit is slowly erected. Then comes another period of stimulation to the local mining industry, for the amount of capital available is increased by the loans obtained by the operators from the banks and from the public, through the medium of stock

issues. The introduction of a credit system enhances local prices.

Is not this true of the world at large? Civilized peoples do about 90 per cent of their business on credit; whether in the form of loans, notes, or checks does not matter; it is done on paper; and only 10 per cent is secured by metallic coin. At the great financial termini, such as New York, 95 per cent of the business of the banks is done on credit; at the division points, such as Chicago, the percentage is less, about 90; and at the branch stations, such as Seattle, the proportion of credit business is still smaller, until on the frontier men want to see "the color of their money." As civilization progresses confidence is established, an enormous and increasing proportion of transactions is effected by exchange of credits, until relatively only a few bars of bullion or a few sacks of gold serve to remind us of the small basis on which our pyramid of credit is reared. Panics diminish credit temporarily and make a call on reserves of gold coin. With diminution of credit gold appreciates and commodity prices go down; during periods of free credit and consequent expansion of trade, gold is less in demand for banking, and commodity prices advance. At the present time gold production is nearly stationary, the increased yield of South Africa balancing the diminished output of Australia and America. Credit shrank during the panic of 1907 and has not wholly recovered, the banking centres have withdrawn gold from the channels of trade, the index number of commodity prices has fallen from 2601 in June 1907 to 2168 in September 1908. This can be expressed in another way: the market value of a commodity is the number of dollars it fetches, that number is directly dependent on the demand for the commodity; if a man possessing credit does not utilize his credit, the demand for commodities declines; if he is impelled to make the most of his credit, he buys and prices advance. What makes men use their credit and become expansive—and expensive? The world has been going through a period of industrial development and consequent commercial activity. On the American continent especially the spirit of a people occupied in rapid and extravagant utilization of extraordinary natural resources has stimulated the desire to spend and be spent. New enterprises, promising inventions, fascinating opportunities for 'making money' rapidly and easily have led to the fullest use of the credit factor. In the interval the gold production has increased—for example, it has doubled in the last ten years—but while the proportion of increase has been remarkable, the aggregate of gold added to the world's stock has been relatively small when compared to the vast expansion of credit and the tremendous increase of business.

State Mine Inspection.

Mining has been little hampered in America by statutory regulation or by the mandates of inspectors. Few States possess such regulations, and fewer pretend to establish official inquisition of precautionary measures for preventing accidents in mines. Montana has taken the lead among the metal-mining

States in exercising control in this regard, and Pennsylvania among the coal-mining States has elaborated a system of rules and inspection to a higher degree of efficiency than any other. A bill has now been introduced into the California Assembly for the appointment of an inspector of mines; this is a symptom of awakening interest in a subject that is likely to command increasing attention. Such measures are capable of harming industry, if the powers conferred be not carefully guarded, or of becoming a farce, or worse still, a basis for graft. In the case of the California bill the fairest criticism would seem to regard it as premature. It would look like an attempt to provide a sinecure for some political favorite did not Section 11 naively lay the prospective incumbent open to be "sued upon and recovery had thereon by any person aggrieved, injured, or damaged by reason of the failure by said inspector to perform the duties herein required." Moreover, the proposed act invests the inspector with no authority; he can recommend but cannot command, and no penalty attaches to disregard of his suggestions. The only semblance of compulsion lies in the fact that failure to comply would constitute *prima facie* evidence against the operator in the event of an accident. The appointment of a mine inspector without power would be to create a ridiculous supernumerary to be fed at the public crib; to endow him with authority unrestrained by specific regulations enforceable under adequate penalty would be to let loose an autocrat who would inevitably discover a money-value for mildness in his edicts. California has not yet taken the question of mine regulation seriously. The statute-book is cumbered by a feeble coal-mine act, passed in 1874, that would provoke a smile from infant Oklahoma; another earlier act prescribes an alternative exit from a mine more than 300 feet deep in which as many as 12 men are employed; one passed in 1893 provides for a uniform system of mine-bell signals; and there is another making it a misdemeanor to leave an abandoned shaft or pit uncovered or unfenced. It would be easy to point out many absurdities in Assembly Bill No. 294, but the passage of such an act in advance of legislation defining the duty of mine-owners in the protection of employees is not to be anticipated. As it stands, it pretends to require the inspector to discriminate between experienced and inexperienced operatives, without establishing a basis for ascertaining competency.

Legislation of this character needs to be well advised, or damage will ensue far worse than could arise from trusting to the instinct of self-preservation on the part of the miner, and to the instinct for avoiding damage suits on the part of the mine owner. The subject might properly engage the attention of the Mining and Metallurgical Society of America. Increasing pressure for restrictive legislation will lead to the passage of crude acts in many States unless intelligent guidance be given. Examination and discussion of the best examples of mine regulation abroad would furnish material from which lawmakers could draw for the framing of rational statutes applicable to American conditions.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

T. H. LEGGETT is in Mexico.
BEN. B. LAWRENCE is at Cobalt.
J. E. SPURR is at Matehuala, Mexico.
HENRY F. LEFÈVRE is at Beatty, Nevada.
FRED L. MORRIS is on his way to New York.
J. MORGAN CLEMENTS was at Baltimore recently.
W. W. ADAMS now resides at Oakland, California.
J. W. MERCER has returned to New York from Ecuador.
CHARLES T. MIXER is examining mines in Sinaloa, Mexico.
E. H. GARTHWAITE has returned to Oakland from Durango, Mexico.

FRANCIS DRAKE has been examining borax deposits in southern California.

JOHN O. NORBOM, lately in South Africa and Norway, has returned to California.

C. W. PURRINGTON is in the Mediterranean and will reach London on January 24.

O. B. PERRY is expected in New York on his return from Europe about January 22.

J. W. BRYANT, of the Tyee Copper Co., was in San Francisco on his way to Mexico.

SIDNEY JENNINGS has been appointed consulting engineer to the Boston Consolidated, Utah.

D. A. McDONELL, manager of the Butters Copala mines, in Sinaloa, Mexico, is in San Francisco.

EDWIN A. AUSTIN, on his return from the Yukon, has gone to Colombia, to return in a couple of months.

HERBERT HAAS has resigned from the Union Iron Works and will resume consulting metallurgical practice.

T. H. OXNAM has just returned to Los Angeles from the Gold Mountain mines, San Bernardino county, California.

A. E. DRUCKER, lately metallurgist for the Oriental Consolidated Mines Co., has left Korea on a tour of the world.

ALEX F. REID, lately assayer and metallurgist to the Montana Mining Co., is at present at Victoria, British Columbia.

MARK B. KERR has been appointed consulting engineer to the Pittsburg Gold Flat Mines Co., near Grass Valley, California.

ROBERT A. KINZIE, general manager of the Alaska-Treadwell mine, was in San Francisco this week, on his way to Washington.

H. C. SCHMIDT has resigned from the management of the Cia. Metalúrgica Nacional, of Matehuala, and has opened an office at Monterrey.

E. C. KNOWLES and PAUL W. AVERY, of Deadwood, South Dakota, are in San Francisco on a month's leave of absence from the Homestake.

WILLARD S. MORSE has not resigned from the A. S. & R. Co.; it is his son Willard V. Morse, who was at the Aguascalientes smelter, in Mexico.

H. A. SHIPMAN leaves for London in a few days. He will proceed to the Gold Coast Colony, West Africa, where he has accepted a year's engagement.

A. P. LOW, R. W. BROCK, W. G. MILLER, and F. D. ADAMS attended the Baltimore meeting of the American Association for the Advancement of Science.

The Colorado Scientific Society held its annual dinner at the University Club, Denver, on January 2. FRANKLIN GUTTERMAN, the president, was in the chair.

F. O. HARVEY and A. G. B. WILBRAHAM have entered into partnership as consulting mining engineers, with offices at 2 Laurence Pountney Hill, London. Both have been connected with the Mason & Barry copper mines in Portugal, Mr. Harvey some years ago and Mr. Wilbraham more recently.

General Mining News.

ALASKA.

On Cooper gulch there has recently been found an old river channel which is reported to be both rich and extensive. The finders, A. Jorgenson and R. E. Sutherland, believe this river channel to have been the source of the rich third beach of the Three Star claim.—There is increased activity this year in the Willow Creek district. Some Oklahoma capitalists operating the Gold Quartz Co. have bought a property from Bartholf Bros., on which they have erected a small stamp-mill. Bartholf Bros. expect to open up their Gold Wonder mine in the spring with a 3-stamp mill. McCoy & Thomas, owners of the Gold Bullion mine, have let a contract for running a 100-ft. adit and for the erection of a stamp-mill.—A 10 days' run brought 66 oz. of bullion to the three men operating O. G. Herning's placer mine on Grubstake gulch.—Robert Compton spoke most enthusiastically of the Fairbanks district on his return from Valdez. He has been working No. 5 Below on Little Eldorado creek, and was much encouraged by the discovery of large nuggets, some of which weighed as much as 20 oz. each. He is convinced there are still big things to be found, and instances Goldstream, No. 17, and Engineer creek as rich properties which were passed over by thousands in past years.

ARIZONA.

COCHISE COUNTY.

A short time ago the Calumet & Arizona Co. started development on the Hope and Wagner claims which adjoin the property of the Shattuck Arizona Copper Co. A 2-compartment shaft is being sunk, and will be carried to a depth of perhaps 700 ft. Drifts will be run to explore the ground at the same depth in which the orebodies have been found in the Shattuck on the northwest and Pittsburg & Duluth on the southeast. The copper production of the C. & A. smelter at Douglas for the last two months has been unusually large, approximating 5,000,000 lb. per month. The new 500-ton furnace installed a few months ago has been working splendidly, which accounts for the extra tonnage smelted, while the large body of high-grade oxide ore on the 1300-ft. level of the Hoatson has added materially to the copper production.—The excellent recent ore developments in the Superior & Pittsburg mines have again started rumors of a possible combination of the S. & P. and C. & A. properties, both being at present under the same management.—A considerable increase was recently made in the working force of the Shattuck Arizona Co., and since that date regular shipments of ore have been made to the Copper Queen smelter at Douglas. Since active work has been resumed more high-grade ore has been found on the 600-ft. level, which may be a continuation of the large orebody already developed to a good extent. The regular annual stockholders' meeting of this company will be held in February, when it is believed the final decision will be made upon the erection of a smelter at Douglas.—For several months there has been considerable activity in the Courtland district. Four companies are operating there employing about 250 men. These companies are the Copper Queen, Calumet & Arizona, the Great Western Mining Co., and the Leadville Mining Co. The first three are operating two shafts each, and the ore developed in the entire district is satisfactory. In the Mary shaft of the Great Western Co. good-sized bodies of high-grade oxide-ores have been found.—The Commonwealth mine is running 20 stamps and five rolls. They are hoisting 125 tons out of the B shaft, and quarrying out 70 tons in an open-cut, making 200 tons per day. The big cave of last year was a blessing in disguise, as J. Metcalf, the superintendent, has pulled 40,000 cars out of a single shoot for filling. They are working \$3 ore at a fair profit, as the labor sheet shows a cost of 83c. per ton, including hoisting and timbering. About one-third of the tonnage goes

direct from the rolls to the cyanide plant.—The Copper Belle is shipping 80 tons of sulphide ore per day to the Shannon smelter, and is piling up an extra supply in case of emergency.

GRAHAM COUNTY.

I. N. Stevens reports that while doing assessment work on the Kentucky claim, owned by Julius Lexinsky, of New York City, a strike of copper glance ore was made. On the property is an adit now in 225 ft., which will be lengthened to 250 ft. before a cross-cut is driven to determine the extent of the copper orebody. The Kentucky claim is near Garfield and not far distant from the property of the Stevens Copper Co.—F. S. Hoyt has so successfully operated the cyanide plant on the tailing of the old Silver King mine for several months past that he is preparing to increase the capacity from 30 to 60 tons per charge.—The Copper Creek Mining Co., under the superintendence of R. Roy Sibley, has made good progress during the last two months. The two-compartment shaft of the American Eagle has been completed to the 200-ft. level, and a station is being cut at this point, which will include pump station and sump. Timbering has been completed, and the shaft

The Start of a New Camp.

started below the 200-ft. level, three-compartment in size. The mill-site is ready for excavation work; nearly all the machinery is on the ground, and the power-plant is fully equipped.

CHIA COUNTY.

The events of the week in Globe were an important strike of sulphide ore in the Gray mine, the ratification of the contract for the sale of the Inspiration mine to the Gunn-Thompson interest, and the completion of the first payment of \$250,000 on the property; and the placing of the order for machinery for the smelter which the Arizona Commercial Copper Co. is to build.—The Inspiration Mining Co., of which William B. Thompson, of New York, and George E. Gunn, of Salt Lake City, now have control, is a promising copper property adjoining the Miami mine on the southwest, and is reported to have over a million and a half tons of sulphide ore blocked out.—A company has been organized to take over the option held by H. B. Hovland on the Live Oak group of claims, about six miles west of Globe. The organizers of the company are Henry B. Hovland, Hoval A. Smith, D. L. Fairchilds, and Walter A. Barrows, and the indications of their development work gives them every hope of success.—There is a movement on foot in Globe to secure for the mines a part of the electric power shortly to be generated at the Roosevelt dam.

MARICOPA COUNTY.

W. W. Wishon expects that the Central Arizona Electric Power Co., of which he is manager, will be ready to deliver power in about 60 days. The plant has been designed and is being erected by the Chicago firm of Evans, Meisse & Co., and will develop 1200 hp., with the probability of the addition of a further 500 hp. in six months. The greater

portion of this power will be used by the Octave Mining Co., the remainder to be sold to irrigation companies and for the lighting of the town of Wickenburg at the rate of \$150 per horse-power per annum. Even at that rate it is believed that this will afford a saving of 20 to 40% over the present cost of generating power with fuel oil.

YUMA COUNTY.

A party, under the leadership of George Mitchell, president of the Clara Consolidated G. & S. Mining Co., recently visited their property, situated some 16 miles from Bouse. The company owns 155 claims of copper-bearing land, the development of which has justified their starting to build a smelter to treat 350 tons per day, and they further hope to bring in the railroad to the mines from Bouse. The party contained among others, George A. Treadwell, of New York, George Mitchell, T. Carrigan, T. P. Cullen, and R. E. Morrison.

CALIFORNIA.

ELDORADO COUNTY.

The new slate mill at the Eureka quarries at Slatington has started work recently and is now working on a car-load order for an electrical concern in San Francisco. The quality of the product is said to be first class.—It is rumored in the Georgetown district that the Loon Lake Water & Power Co. is about to dispose of its holdings to a company of New York capitalists.—A new 2-stamp mill has been installed at the Independence mine and placed in commission. A 20-hp. gasoline engine furnishes the motive power. The mill was erected by George M. Ure, of Placerville.

SISKIYOU COUNTY.

(Special Correspondence).—The Blue Ledge mine, situated in the Siskiyou mountains, near the headwaters of the Applegate river, has about two miles of development in the shape of adit levels, parallel drifts, winzes, and raises, on a north-south mineralized zone that strikes along a contact of mica-schist with a dark-colored schist. The zone of mineralization is 60 ft. wide in places, extending from the dark schist as a foot-wall into the mica schist. The bulk of the ore is a chalcopryite, accompanied by gold and silver, resembling in grade and character the Mammoth ore at Kennett. There are nine adit levels running southerly, the longest being 1300 ft., making a depth of 600 ft. between the highest and lowest workings; another adit has been driven northerly from the main base of operations. No stoping has been done, though there are 30,000 tons of ore on the dump as the result of development work alone. F. W. Carnahan, superintendent of the property, considers the ore well adapted to the requirements of a copper smelter, without the addition of ore from an outside source. It is presumed that a smelting plant may be erected before long, though it is understood that no definite steps in that direction have been taken. The Blue Ledge belongs to Robert S. Towne, who is operating mines at Sierra Mojada and Santa Barbara, and a smelter at San Luis Potosí, Mexico. Other properties have been developed to some extent in the Blue Ledge district, the work on them all aggregating about 2000 feet.

Yreka, January 16.

TUOLUMNE COUNTY.

Roger Knox assumed the superintendence of the Black Oak on New Year's Day in place of M. A. Knapp. He is now engaged in unwatering the mine, which has already been accomplished down to the 600-ft. level. Meanwhile the mill is being run from ore from the dumps.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A strike has just been made on the Ajax property, on Leavenworth Mtn., operated by the Big Indian M. Co. The discovery was made in driving the lower adit, a body of smelting ore being uncovered, which is now being placed in condition for stoping. Edward Butts, who is manager, states that shipments will be

started during the next few days.—M. J. Riley, leasing on the Sunburst, has started a shipment of 300 tons of 'cobblings.' The west drift from the Grant level has been driven 75 ft. and stoping has been started. There is exposed a streak of smelting ore that is from 6 to 14 in. wide, which assays 204 oz. silver per ton.—A campaign of development has been put under way upon the Paragon group of claims, on Sherman Mtn. An adit has been started which is now in 20 ft. E. W. Shepard, the manager, states that machinery will be installed in the early spring.—A number of lessees holding privileges on the Phillips vein, cut by the Burleigh adit, are to resume operations. Work was suspended about a year ago, at the time the undertaking was put under way. As a diamond-drill is in use, the leasing work will not interfere with the operations being carried on by the Dives-Pelican and the Seven-Thirty M. & M. Co. The block of ground held by Dearstyne & Hancock contains ore of good grade, the streak being from 8 to 20 in. wide, worth \$40 to \$45 per ton in silver and lead. There is also showing a body of lead-zinc ore that can be mined and milled at a profit. Shipments of the last named product will be made to the custom mills in the lower end of the county.—Barney Barncassie, leasing on the Columbia, Silver Mtn., has started shipments of smelting ore. The product is being sent to the Georgetown sampler and is worth from \$35 to \$40 per ton in silver and gold. Stoping is in progress and a streak of ore is being followed that is from 6 to 10 in. wide. The property is controlled by W. A. Maxwell, of Georgetown.—Within the next ten days the force of men employed at the Black Eagle mine, on Chicago Mtn., will be increased. J. F. Puchert, the manager, has made a number of improvements, and from this time forward a heavy tonnage of ore will be extracted. This mine has been developed by a shaft sunk to a depth of 585 ft., while drifts have been run at each 75-ft. level. The longest drift is on the sixth level, having been advanced for 310 ft. In the breast there is exposed 10 in. of lead ore that is worth from 1 to 2 oz. gold, and from 30 to 70 oz. silver per ton. The compressor plant recently purchased is now being connected and some time during the next two weeks machine drills will be brought into use. The aerial tramway running to the base of the mountain, 6000 ft. distant, will probably be completed within 30 days, or by the time the new mill is ready to be put into commission. The mill is being equipped with rolls, screens, tables, jigs, in addition to an electro-chemical process. A set of Triplex rolls with a capacity of 100 tons per day has been purchased. This is the first time that this piece of machinery was ever installed in Clear Creek county.—The Choctaw property, on Saxon Mtn., is to be consolidated with the Miller group of claims. The Miller adit will be continued to the Choctaw vein, which produced about \$75,000 from a shaft sunk to a depth of 60 ft., with comparatively little driving and stoping. The objective will be reached within 130 ft. The Miller vein is an extension of the Choctaw to the west and some high-grade ore was mined a few years ago from the upper workings.—Driving the west drift of the Ramsdell is in progress, and this week a streak of lead ore was cut that is from 10 to 14 in. wide. Assays indicate 2 oz. gold, 35 oz. silver per ton, and 32% lead. It is understood that a campaign of development is to be carried forward during the present year. G. W. Teagarden is manager.—The Mollie Gibson group of claims on Saxon Mtn. is again undergoing development by Chad. Kline, the owner. The adit is being driven and it is expected to intersect another vein within 30 to 40 feet.

Georgetown, January 16.

GILPIN COUNTY.

It is reported that steps are being taken for the reorganization of the Grand Central Mining Co., formerly known as the East Whiting, on Gunnell hill. The property is equipped with a first-class plant, including an air-compressor.—A boiler plant has been taken to the German mine, operated by the German & Uranium M. Co. The company will install a large hoisting plant and erect a

new shaft-house, and they are also interested in the Leone and Empire mines, farther west on Quartz hill.

SUMMIT COUNTY.

The mill of the Wellington Mines Co. is nearing completion. The crusher and rolls have been installed, the jigs are being built, the tables are about ready, and every line of work is proceeding at a satisfactory rate. An adit to connect the mill with the Oro workings lacks only a hundred feet of completion, and both should be ready about the same time.

TELLER COUNTY.

James McIlwee, the superintendent of the Roosevelt drainage tunnel, is employing a selected gang of men to drive their heading at a maximum rate. When working with two shifts, an advance of 113 ft. was made in the first seven days of the present month. They have been using a pair of the No. 6 Water Leyner drills, which make from 24 to 30 holes per day; and to effectively break this hard Pike's Peak granite they charge their holes with either an 80% dynamite, or with 100% powder, containing 92% nitroglycerine and 8% guncotton, made by the Dupont Powder Co., of New Jersey. Taking into consideration the fact that the heading has an area of about 70 sq. ft., McIlwee is in hopes of making a new monthly world's record.

IDAHO.

BOISE COUNTY.

The Gold Hill mine, which has been one of the most productive gold mines in this district, is letting leases on its upper workings. This property has been in litigation for several years, but has recently been purchased, and is now consolidated with the Iowa Mines, as the Gold Hill & Iowa Mines Co., with E. E. Carter as manager. It is the intention to lease all the workings above the water-level and to make suitable arrangements with these lessees to treat their ores in the Iowa mill.

IDAHO COUNTY.

Idaho Central Mining Co., of Spokane, which has been developing the Alberta mine in the Elk City district under a bond, has made the last payment to Marsh Bros., and taken full control of the property. The group consists of five claims, 12 miles southeast of Elk City. The Alberta is one of several groups of properties that lie adjacent to each other, which were taken under bond recently by J. B. Weimer, of Salt Lake City. On the Alberta the main working shaft is being sunk on the foot-wall side of the vein. Cross-cuts will be driven and levels opened up every 100 ft. The company will endeavor to get the shaft down 300 ft. by June 1, and will soon install a hoisting plant of 1000 ft. capacity. Accommodations for 25 men, and also a wagon-road have been constructed. A. W. Boyd is manager of the property.—C. E. Svenson has sold his Golden Scale placer ground, two miles from Elk City, to P. J. Jennings, of Portland. The placer is an old river channel with a maximum depth of 70 ft. to bedrock.

SHOSHONE COUNTY.

(Special Correspondence).—Work is about to be resumed on the property of the North Franklin Mining Co., operating a group of claims adjoining the Star and the Morning mines in the Mullan district. The annual meeting of stockholders was held at Wallace at the beginning of the week and the officers elected for the ensuing year. The property will be managed by Norman Ebblev. It was decided at a later meeting of directors to levy an assessment of five mills per share.—According to a statement issued by the Reindeer Copper & Gold Mining & Milling Co., \$25,000 was spent during the past year on development. The treasury is depleted at the present time, but an assessment of five mills per share has been levied by the directorate. Throughout the year development has been confined mainly to the driving of a 2800-ft. adit designed to give a depth of 1000 ft. This adit has now been driven about 2062 ft. The property is fully equipped with machinery and has a good showing in the upper workings.—Work has begun on the Copperhead mine in the Look

out district, and it is expected that a sample car of ore will be shipped to the smelter in the near future. The old adit, which had been driven a distance of about 300 ft., has been abandoned and another started to cut the main lead at great depth. The ore carries lead, silver, and copper.—All arrangements have now been practically completed for the erection of the new smelter in the North Fork district. A site has been secured and it is the intention of the company to erect a plant of 100 tons capacity to handle the copper ores of the north side. Contracts have been made with the Handspike and the Horst-Powell mines, according to the terms of which the smelter is to be running by October 1 of this year. Maurice Blanchard, whose patents will be operated in the new plant, states that it is the intention to commence active work on the erection of the plant as soon as the snow clears in May. In addition to the contracts referred to Mr. Blanchard states that enough ore has been promised to keep the plant busy all the time. If the new process proves a suc-

Boundary and Coeur d'Alene Districts.

cess it is the intention to erect other plants for the treatment of both lead and zinc ores.—The Ambergris Mining Co. has increased its capitalization from \$1,500,000 to \$3,000,000. The property recently became involved in litigation with the adjoining Hercules mine, but all claims were adjusted out of court. By the terms of the settlement the property will be developed through the workings of the Hercules mine, the owners of which will expend about \$75,000 on the Ambergris property.—A circular has been issued by the trustees of the Lucky Calumet property warning stockholders not to part with their stock to firms of Eastern stockbrokers who are advertising for the stock and offering the highest market prices. It is believed that some Eastern syndicate is attempting to secure control of the property and that 200,000 shares have already passed into their hands.—Arrangements have been made by the Pittsburg Lead Mining Co., which has just resumed work, by the terms of which each stockholder will advance money to the company in the ratio of five cents for every share of stock held. In this way sufficient funds have been raised for the continuation of work all winter. The financial statement issued by the company shows that there is at present \$145 on hand.

and stock valued at \$62,746 still remains in the treasury. The mines and real estate is valued at \$795,805. The equipment is valued at \$52,864, while \$179,930 was spent on development, making a total for the assets and equipment of \$1,092,799. The company's liabilities are said to consist of a total of \$955,692, leaving a surplus of \$137,106.—It is generally believed throughout the Coeur d'Alene that the Federal Mining & Smelting Co. has secured control of the Star mine in the Mullan district for a consideration said to be in the neighborhood of \$1,000,000. The property of the Star company consists of a large number of patented claims adjoining the Morning mine of the Federal company in the Mullan district. The principal owners of the Star company are John A. Finch, A. B. Campbell, I. N. Payton, and Austin Corbin, of Spokane, and Henry Wick, of Youngstown, Ohio. If it is actually the case that the Federal company has purchased this property the mine will probably be developed through the workings of the Morning mine and the ore treated in the Morning mill.

Wallace, January 19.

MICHIGAN.

Isle Royale has temporarily stopped sinking its Baltic lode shaft while concreting the collar. The shaft is bottomed in the formation. Hoisting engines at both No. 4 and 6 shafts are in place and ready for duty. The company is now engaged in installing the compressors. These shafts are slowly increasing their output until now they are shipping 10 cars per day. All the heads at the stamp-mill have undergone a re-construction until now there are three compound heads in operation.—The 650-ft. level has been reached in the Ojibway No. 2 shaft and cross-cutting to the lode is now under way. The levels above have shown the characteristic Kearsarge formation of a rich character, hence no driving or stoping will be done until the desired depth is attained.—Osceola will show in its annual report an increase in production over last year. Nearly 24,000,000 lb. will be produced this year at a considerable profit. With its small capitalization of 96,000 shares, every cent of rise in the metal market is equivalent to \$2 per share to the company. It is expected that in March the new No. 4 North Kearsarge shaft will be making regular shipments to the mill. With the addition of this producer the capacity of the mill will be reached, and it is not at all unlikely that the company will be making provision to increase the milling facilities to take care of the increased tonnage. The North Kearsarge possesses the outcrop of the Kearsarge lode for a distance of 6500 ft. Drifts south from the 37th level of No. 3 shaft will undermine the Wolverine, intercepting the rich ore common to that property. No. 4 shaft adjoins the Ahmeek and drifts from this property and Allouez have cut their richest ore on the Osceola boundary. Drifts from No. 3 shaft to the north have found the richest ground in No. 4's territory. Hence it is safe to assume that No. 4 will have an unusually rich field to work in.—Owing to trouble in sinking its sand-pipe North Lake has not as yet begun drilling. A distance of about 400 ft. has been traversed without striking the lode.—In an endeavor to find the lodes of the Lake and Adventure properties to the north, Elm River is making preparations to cross-cut the formation at the 200-ft. level. In the course of sinking this opening an unknown lode was intercepted, but as yet no exploring has been carried on to prove its value.—A statement has been given out by officers of the Superior company to the effect that the mill-test at that property showed an average of 36 lb. copper per ton for the first day's stamping. This is considered remarkable for the Baltic lode. The average yield from this formation has heretofore kept well in the neighborhood of 20 lb. per ton. It is not expected that the Superior's showing will continue at its present richness, still it has a wide range of fluctuation before the average is reached. Superior's success is notable also as the first outside property in which the Calumet & Hecla has interested itself. It will also serve as a stimulant to further exertions on the part of other mines on the north side of Portage lake who have been

undertaking considerable exploration in hopes of finding the Baltic on their property.—Quincy will show an increase of production in 1908 as compared with 1907. During the latter year 17,796,000 lb. were mined, while it is expected 20,500,000 lb. will have been produced this past year. Last year the company's costs were 11.2c. exclusive of construction, and 12.2c. including that item. Quincy's construction costs will be heavy this year as a result of the expense incurred in sinking the new Pontiac shaft on the Arcadian lands and the construction of the No. 2 steel shaft-house. No. 2 is the company's oldest shaft and produces about 25% of the total product.—The announcement that the option of Copper Range on the Globe tract would be relinquished on February 1 was not unexpected. The vein has made a poor showing ever since development work started. The lowest level has about 500 ft. of drifts, disclosing lode poorly mineralized. Work was commenced in the spring of 1905 and approximately \$500,000 has been expended for exploration. The first shaft had to be abandoned because of quicksand, and the present shaft, 1040 ft. deep, was begun in October of the same year.—What is believed to be the Baltic lode was found several hundred feet farther west than was expected in the fifteenth level of the Atlantic's section 16 shaft. The cross-cut passed through 20 ft. of ore before reaching the hanging wall, and of this about three-quarters is well mineralized. They have started driving in both directions, and are also sinking the shaft below the twentieth level.—The Winona discontinued rock shipments in November 1907, at the time of the break in the price of copper. It is proposed to resume shipments this spring. Meanwhile the directors have had to assess the shareholders for \$2 per share, and will shortly take action calling another assessment, which will probably amount to \$1 per share. The need of these additional funds is due to the extensive development work carried on during the past year, and the fact that less than 13 lb. copper was obtained from the ore extracted.

NEVADA.

ESMERALDA COUNTY.

The new Truitt-Rankin mill at Schurz is now in operation and treating ore from the camps of Granite and Rawhide. The mill is equipped with 10 stamps, amalgamating plates, two California concentrating-tables, and four cyanide vats, each having a capacity of 400 tons. Water is secured from the Walker river and steam power is used.

NYE COUNTY.

It is hoped that the early part of February will see the completion of the custom mill, which L. L. and S. Smith are erecting at Beatty. It is close to the Las Vegas & Tonopah and Tonopah & Tidewater railroads, with which it is connected by short spur tracks. All the equipment is on the ground and the corrugated-iron mill building has been ready some weeks. After coarse crushing the ore will be fed to two batteries of five 1000-lb. stamps, and extraction will be effected by amalgamation and the cyanide process. For this all the machinery has been supplied by Hendrie & Bolthoff, of Denver, and will be run by electricity from the line of the Nevada California Power Co. The Smith brothers have developed their own water supply, which will be ample to supply all requirements for treating 40 tons per day.—Two hundred tons of ore have been obtained by Charles Newton, ore purchaser for the Springdale custom mill. This ore will be used to test the machinery before it is opened to general use on February 1.—It is reported that L. P. McGarry and G. S. Johnson, of Goldfield, are considering plans for the construction of a mill for the Bullfrog West Extension Co. The plant will be designed for a capacity of about 50 tons per day.—The output of the Tonopah mines for the week ending January 16 totaled 5173 tons, of an estimated value of \$129,300.

LANDER COUNTY.

The consolidation of 154 different mining claims by W. W. Wishon into the Austin-Manhattan Consolidated Mining Co., is the forerunner of much expenditure for mine de-

velopment and equipment. They already have many shafts, a long adit, and several cross-cuts, and mean to install a modern stamp-mill for the treatment of their \$10 and \$15 ore. D. C. Boley is manager of the present mill, and Marvin W. Ditto is consulting engineer.

LINCOLN COUNTY.

Owen A. Bally, president of the Pioche Demijohn Mining Co., has called a meeting of the directors to take action on the matter of providing better mine equipment. The horse-whim is to be replaced by a gasoline engine and hoist; it is also the intention to install a compressor in order to substitute machine-drilling for hand work.

LYON COUNTY.

A combine of three of the big leasing companies of Granite has been made and J. H. Boney, of Los Angeles, has become interested. He will assume the management of the combined interests and procure a hoist, to sink the Graham shaft to a depth of 500 feet.

WHITE PINE COUNTY.

In order to finance an extension of the Steptoe smelter and mill the Nevada Consolidated Co. has sold to a Boston syndicate the remainder of the 125,000 treasury shares of the Cumberland Ely, at a price not far from the present market price.—There is some indication of the high regard in which mining property is held in the Ely district, as demonstrated by the fact that over 200 final receipts for patents on claims were secured during the year. At the present time all groups of any considerable size between the McDonald Ely on the east and the Boston Ely on the west, a distance of 8 miles, have been patented.

SOUTH DAKOTA.

CUSTER COUNTY.

(Special Correspondence).—The mining outlook in the southern Black Hills at present is encouraging, and although the recent cold wave (20° below) has temporarily restricted prospecting and mine development, yet there is promise of a fair output of precious metal during the coming season. The circumstances surrounding the mines in the southern Black Hills are somewhat peculiar. The veins for the most part are in the Archean micaceous slate between intrusive granite. The schistosity runs northwest and these belts of veins run with the formation. These quartz veins are inclusive generally at an angle of 60 to 70° from the horizontal. The veins are sometimes in contact with the granite, but sometimes both walls are slate. These 'formation veins' (as they are locally called) are generally low-grade, and usually assay from \$2 to \$7 gold per ton. They are from 6 to 40 ft. wide, and in the larger ones the ore often consists of alternating quartz and slate, with iron oxide. There is also another class of veins running northeast cutting the slates nearly at right angles. These are nearly perpendicular, and are usually from 1 to 5 ft. wide. They would be classed as high-grade, as the ore will yield from \$5 to \$500 per ton in gold. There is no silver, copper, or lead worth mentioning in this district, although there is scarcely a mine entirely free from one or the other of these minerals. The veins are all free-milling at the surface and in some cases the free gold persists to quite a depth, but usually becomes more and more base as depth is attained, when it will not amalgamate and the gold ceases to be amenable to the free-milling process, and the cyanide process is required. The Saginaw is the leading mine in the district, with a capacity of 50 tons per day, fully equipped for cyaniding. The mill has 22 vats with Wilfey concentrators and slime-tables. The last clean-up showed an average of \$41 per ton in gold. These veins are each from 3 to 4 ft. wide, and the company is on the high-road to prosperity. I. W. Herber is manager.

The Ruberta Mining Co., owning a property situated 4 miles west from Custer, is now equipped with 10 stamps and vats for cyaniding. The plant will be operated on ore from the Ruberta (formerly the Old Charley group of claims) and it is announced by W. W. Olds, the superin-

tendent, that they will start the mill about March 1. The main vein is well developed and ready to supply ore for a steady and continuous run. The Clara Belle, situated about 9 miles north of Custer, an excellent producer of the precious metal in the past, is now idle on account of the caving of the old works. The company forsook the old incline and sunk a new vertical shaft to intercept the vein on its dip, but never found it. The property was recently sold by the receiver and was purchased by some of the largest stockholders for \$28,000. They have formed a new company, which will commence cross-cutting to find the vein. The orebody was never continuous, but consisted of large irregular lenses. H. Dole is in charge of the mine.

The Ivanhoe, situated about 8 miles northeast from Custer, also produced high-grade gold ore. It is idle at present and will probably remain so until spring. Herman Ratte, the manager, has gone to Pierre to attend to his duties as State Senator. The mine is equipped with a 5-stamp mill, for testing purposes, and a Chilean mill of 50-ton capacity, but as the ore is hard quartz, it has been found that it will crush only about half that much. The Westinghouse Electric Mfg. Co. is running with full force on its mica mines about 6 miles west of this place, where they employ 100 workmen in the mines and in the splitting and trimming departments. They own the New York and the White Spar mica mines, and several others only partly prospected. They are building a store at the mine, enlarging their boarding-house, and erecting cottages for the accommodation of the workmen and their families. A large vein of fine mica exists in the New York, and another in the White Spar. John Pyne is manager. The Amblygonite mines near Custer are not producing at present, the company mining that material having transferred its activities to Keystone, about 16 miles northeast. The reason given for the removal is that the mines at Keystone are richer and yield about 8% lithia phosphate. The material is shipped to Omaha, where it is prepared for use. The factory in Omaha is in charge of Herman Reinhold. Edward Davis has charge at the mines, the post-office address being Custer.

Custer, January 15.

CANADA.

BRITISH COLUMBIA.

The precise figures of the mineral production in the Province of British Columbia for the 12 months of 1908 are not yet complete upon the Government records. E. Jacobs, of Victoria, B. C., has, however, made a conservative estimate of the production from data on hand, which is as follows:

Gold, placer, 34,000 oz.	\$882,000
Gold, lode, 256,000 oz.	5,291,520
Silver, 3,637,000 oz.	1,518,500
Lead, 34,775,000 lb.	1,654,695
Zinc and iron, 10,000 tons.	280,000
Copper, 43,885,000 lb.	7,792,820
Total	\$15,219,535
Coal, 1,700,000 long tons.	7,450,000
Coke, 248,000 long tons.	488,000
Building material, etc.	2,000,000
Total	\$22,857,535

The total for the year ending December 31, 1907, was \$25,882,560, so that the production for 1908 shows a decrease of \$2,025,025, the shrinkage occurring in the production of lead and copper. The activity displayed at Flathead in boring for oil during the past fall and summer has had to be suspended owing to the heavy snowfall and intense cold.—It is expected that the Sullivan Group Mining Co. will be reformed at the next meeting of the shareholders, and operations at the mine and smelter resumed at an early date.—The Molly Gibson, in the Burnt Basin, owned by C. Schwartzenhayer and others, recently shipped a carload of 28 tons to the Trail smelter, which netted the gratifying return of \$20 per ton.

Special Correspondence.

TORONTO, CANADA.

Output of Cobalt. — Concentration of Ore. — Sale of the O'Brien. — The Crown Reserve. — Gowganda District.

The output of Cobalt sent to the smelters during the year just closed amounted to a total of 25,463 tons, as against 14,851 tons in 1907. These figures do not adequately represent the increase in silver production, as during the year the Buffalo and Coniagas mines installed concentrators. Cobalt Central is now concentrating on a large scale, and the McKinley-Darragh will shortly have a concentrating mill in operation. Several other mines are also disposing of their low-grade ores to custom concentrators on the ground. But for the low price of silver the output would have been considerably larger, as many of the mines have pursued a conservative policy in restricting the immediate output. The list of shipping mines, 32 in number, is headed by the La Rose with 4715 tons, the second place being taken by the Nipissing, which shipped 3557 tons, the O'Brien coming third with 3428. There have been frequent reports as to negotiations for the sale of the O'Brien to a syndicate, and a few days ago the statement was widely circulated that the deal had finally been closed for \$8,000,000. This is authoritatively denied, and it is further stated that no negotiations for the sale of the mine have taken place.

The new plant of the Temiskaming will be in operation in the course of a week or so. The compressor has a capacity for operating 20 drills. A new dynamo is being installed. The new shaft sunk for the purpose of a main haulage-way is down 150 ft. and will be continued to the 300-ft. level. The mill at the ore-house of the Crown Reserve, comprising a No. 2 Austin crusher with attachments, is running satisfactorily, treating 50 tons of ore per day. The shaft in open-cut No. 1 is down 125 ft. and the vein is found to maintain its width and quality. The north cross-cut from No. 1 shaft has cut several small veins showing silver contents. No. 1 shaft of the Chambers-Ferland is being deepened. At 120 ft. the vein, averaging 5 in. a short distance below the surface, has widened to 18 in. high-grade ore, showing native silver. In the west cross-cut from No. 2 shaft at a distance of 219 ft. low-grade ore 8 ft. wide was encountered, showing calcite, niccolite, and galena. At the Silver Queen extensive development work is being carried on, some 3500 ft. of driving and cross-cutting having been done on the 75 and 150-ft. levels of the main workings. To the south a new shaft is down 75 ft. A sump of a few feet depth will be sunk, a station cut, and underground development undertaken on several promising veins. On the Little Nipissing lease on Peterson lake the shaft is down 150 ft., at which level a cross-cut is being driven to pick up the main vein, along which driving will be carried 50 ft. to strike a rich cross-vein. At the Rochester a great deal of trouble has been occasioned by water, which has delayed the sinking of the main shaft, now down 170 ft. The difficulty has been handled effectively, and good headway is now being made. A good find has been made at the Pan Silver mine in the Temiskaming section of the camp. In the cross-cut at the 100-ft. level a vein was tapped 8 in. wide and assaying about 2000 oz. per ton. At the Otisse mine, in the Montreal River area, a vein which appeared lean on the surface widened at 30 ft. to from 12 to 18 in. and is yielding high-grade ore. A carload of ore has been sacked ready for shipment. On the Clinton location, adjoining the Otisse, a rich vein running from 6 to 11 in. wide has been found. Control of the Kerr Lake mine has been acquired by Adolph Lewisohn of New York. S. S. Rosentamm, Mr. Lewisohn's representative, accompanied by Benjamin B. Lawrence, consulting engineer to the Kerr Lake, inspected the mine this week.

Prospectors and others are pushing forward into the Gowganda district, notwithstanding the hardships entailed by the lack of accommodation. The Canadian Northern Railway Co. is rapidly pushing the construction of the wagon-

road from the end of steel at Sellwood, to Gowganda, a distance of some 50 miles. A force of 60 men and 20 teams is at work and the contractor announces that the work will be finished by the 15th of this month. The Canadian Northern will accept freight from any point in Canada for delivery in Gowganda. It will be forwarded by way of Sudbury to Sellwood, and thence by the company's freight teams to its destination. This undertaking will make Sudbury, rather than Elk City, the base of supplies for the new camp. An expedition will set out this month from Elk City, in charge of Thomas Saville, a noted guide and prospector, who has lived for years with the Indians, in search of a new silver field lying to the west of Gowganda, the existence of which Saville claims to have learned from the Indians. The party will travel with Indian dog-teams.

Reginald W. Brock, formerly a professor in Queen's University, Kingston, who has for some time been connected with the Canadian Geological Survey, has received the appointment of Director of the Survey. He had been acting in that capacity for some time.

MEXICO.

Financial Condition of Republic. — Railroad Earnings. — Oil War. — Mining Law. — El Tajo Mill.

The report of Mexico's Finance Minister, José Y. Limantour, for the fiscal year 1907-08, which has just been made public, is certainly very encouraging to all interested in the welfare of the Republic, for the figures show a total revenue of \$111,771,867, with disbursements of \$93,177,441, leaving a surplus of \$18,594,426. Considering the stringency which has been felt all over the world, and particularly in the United States, during the last nine months of the past year, the results have really been remarkable, for in the history of the Republic this revenue has been exceeded only in the preceding year, and then by but two and a half millions. The years 1905-06 and 1906-07 were the only ones that have shown a larger surplus than that of 1908. It is true that the financial difficulties that came upon the United States were not so severely felt in Mexico until toward the close of the fiscal year, and it is possible that the current year may not show up as well; but, viewed from all points, it is a most encouraging report, and clearly shows that as long as the present régime continues, Mexico's financial condition will be sound and its progress may be considered certain.

Like good results have been shown in other quarters. Attention has been previously called to the large returns continuously made by Guanajuato, El Oro, Pachuca, Chihuahua, and many of the large individual mining properties, and now the Government figures reveal that the combined annual surplus of the National railroad and the Mexican Central has been \$1,003,638 over the fixed charges of the entire merged system during the transition period pending the complete transfer to the new corporation. The natural economy following a complete consolidation should greatly increase this annual surplus. Forty-eight per cent of the freight carried on these roads consists of the products of the mines and of mine-supplies. On this freight it is claimed that no profit is made. The opening of the Manzanillo branch of the Mexican Central through to the West Coast on December 12 was a notable event.

The oil war, between S. Pearson & Son and the Waters-Pierce Oil Co., which was threatened for March or April, and postponed from month to month, does not seem to have broken loose. It is true that the Pearsons have completed their Minatitlán refinery; that the Waters-Pierce Oil Co. has added, or is adding, several million pesos in improvements to its refinery at Tampico, and is acquiring lands in the States of Vera Cruz, Tamaulipas, and San Luis Potosí; and that the Pearsons are establishing agencies in the various important cities throughout the Republic; but it does not appear that there will be any ruinous cut-throat war; it undoubtedly resolved itself into a friendly or understood competition, with a slight reduction in price to encourage a demand and create a market sufficient for both companies.

The Pearson engineers are understood to be making a six months' reconnaissance examination from San Cristóbal, Vera Cruz, across the States of Chiapas and Tabasco to Frontera, on the Gulf coast of Tabasco, near the Campeche line; and rumor has it that a new element has entered into the oil situation in Mexico in the form of E. H. Harriman, who is said to have Ben Andrews, formerly with the Pearsons, making examinations and acquiring lands in various parts of the Mexican oilfields for fuel oil, in connection with his Southern Pacific railroad. The Mexican Petroleum Co., controlled by E. L. Doheny, is figuring on a pipe-line from Vera Cruz to Mexico City, there to make gas from the crude oil and to use the residue for street paving, but as that means heavy lines and pumps, because of the necessity of running the line to an elevation of over 10,000 ft., there is great doubt as to its economic feasibility, as well as to whether the demand is sufficient to warrant such an outlay.

The proposed new mining law, which caused so much comment at home and abroad, and from which the objectionable anti-foreign measures (particularly the famous Article 144) were eliminated, came up before the Mexican Congress on December 11, and though it had many supporters, it also developed stronger opposition than was expected, the main points being that this was not the right time to change the existing law of 1892, and that as the country had prospered in a manner previously unknown under the pres-

Amparo Mill, Jalisco.

ent law, it were better to leave well enough alone; the final outcome was that the new draft was laid over to come up before the session of April, 1909.

In a recent letter it was stated by error that certain improvements were to be made in the mill of the Ayutla Mining Co., which should have been credited to the Tajo, owned by Makeever Bros., at El Tajo, near San Sebastian; the structure of the new mill is ready for the machinery, which is to consist of 10 stamps, concentrators, tube-mill, and cyanide tanks.

JALISCO, MEXICO.

Amparo Mine.—Milling Process.—El Favor.—Casados Mine.

The Amparo Mining Co. has 2000 acres of land in one block, lying south from Etzatlán, the mine being 10 miles from that town. There is a series of veins striking nearly north and south, through a basalt country; they cut through a mountain spur, the two sides of which slope to a deep arroyo on either side. The working shaft is near the crest of the ridge, the mill being in the south arroyo, with the air-compressor and the old adit on the opposite slope. The general offices are on the north side, from which place a good wagon-road leads to the main shaft. A Roebling aerial tramway, about a mile long, carries the ore from the mine to the mill, making a descent of 450 ft. The hills are well covered by a young growth of oak trees, adding to the attractiveness of the surroundings; some eucalyptus trees have also been planted on the tract. The company employs about 800 men—350 in the mine, 150 about the mill, and 300 as freighters, wood-chopeprs, and ranchers. The mine was operated 75 years by Mexicans before it was sold to the Amparo company, during which time the richer pay-streak was mined, but alongside was always left a good body of what now constitutes milling ore. The former

operators entered the mine through an adit driven on the vein. The new company greatly extended the workings from this adit. The adit follows the vein 800 ft., at which point the vein divides; here the work continued 1000 ft. on the east and 2000 ft. on the west branch. The west vein carries the better grade of ore. At 1000 ft. from the point of divergence a fault occurs, the displacement throwing the west vein about 18 ft. westward. Beyond the fault-plane the vein retains its vertical position; and here a remarkable body of ore was opened that is said to measure 600 ft. long, 250 ft. high, and from 3 to 14 ft. wide. The west vein on the south side of the fault is 40 ft. wide in places. Important work has been done on the east vein south of the fault. The main shaft has three compartments and is 750 ft. deep, connecting with the main adit-levels at 500 ft. A winze has been sunk 400 ft. from the adit, and a drift has been run from the bottom of the winze to a point under the shaft. The latter will be sunk to connect with it. This gives a vertical depth of 900 ft. James H. Howard, general manager for the company, states that a sufficient tonnage of ore is in reserve to keep the mill in operation 10 years; and that the property is paying a net profit of

Tramway Terminal, Amparo Mine.

\$30,000 per month. Besides the ore blocked out there is a dump of 40,000 tons claimed to assay 450 gm. silver and 11 gm. gold per ton, available for milling. The mill, under the superintendence of William Howard, formerly of El Oro, has 50 stamps, each weighing 1050 lb., dropping 6½ in., 108 drops per minute, crushing 3½ tons per stamp per 24 hr., through 30-mesh screens. The pulp from the batteries is classified by hydraulic classifiers, the fine passing to Johnson vanners and the sand to Wilfey tables. The concentrate made by the tables is re-concentrated by a table specially regulated for this work. The table-tailing goes to sand-collecting tanks, and the vanner-tailing to slime-settlers made of cement. The sand from the collectors passes to sand-treatment vats where a 0.3% cyanide solution is applied. This is followed by a wash every 2 hr. for 5 days, a solution of the same strength being used. Then follow 2-hr. washes for 3 days, with a solution of 0.1% KCy. In the first series of washes lead acetate is applied. The slime is treated in tanks, having Butters mechanical agitators. These are charged with one-third slime and two-thirds solution, the latter having a strength of 0.15% KCy, lead-acetate being added also. After agitating 6 hr. mechanically, and 3 hr. by centrifugal pumps, the slime is settled and the solution decanted. Three more washes follow, 0.1% solution being applied. Each charge in the slime-tank gets 27 hr. mechanical agitation, and 9 hr. aeration by centrifugal pumps. This method will be modified later by the use of Burt filters. The precipitation takes place in zinc-boxes of the usual style.

An analysis of the ore shows the following constituents: Gold per ton, 10 gm.; silver, 450 gm.; lead, 0.3%; iron, 2.9; copper, 0.1; zinc, 0.7; sulphur, 0.5; manganese, 0.9; calcium, 8.5; silica, 74.2; alumina, 1.2. The concentrate sold contains 11.9% iron, 3.4 lime, 9 zinc, 12 sulphur, 9.6 lead, 34.6 insoluble, 464 gm. gold, and 9229 gm. silver per ton.

In the total gold recovery, 35.97% is in the concentrate, and 61.3% in the precipitate; of silver, 18.9% is obtained in the concentrate, and 68.1% in the precipitate. The total extraction represents 97.7% of the gold and 87 of the silver, as shown by the assay values. C. W. Lininger, who took the superintendency of the mine several months ago, states that mining costs are gradually being reduced; for one month recently the cost was ₧3.41 per ton of ore mined. This, it is explained, included little, if any, development work. It is announced that the property will have electric power connections in the next few months, and will then be equipped to use it.

El Favor mine, in the Hostotipaquillo district, 40 miles northwest from Etzatlán, is controlled by Makeever Bros. and their associates, with D. M. Munro as manager. In the holdings are 180 pertenencias, having one principal vein, and several minor veins, in rhyolite. The vein consists of quartz and altered rhyolite, averaging 700 gm. silver and 3 gm. gold per ton. The silver occurs mainly as sulphide, with some chloride and bromide. The ore also carries 11 to 12% iron sulphide, with some manganese. The mine is opened by a series of cross-cuts to the vein; a 1200-ft. adit, now 800 ft. long, is being driven, which will cut the ore 600 ft. below the surface and 400 ft. below the present workings. In all, there are 5000 ft. of development. Equipment for a 20-stamp mill is being installed. It will include Wilfley tables, vanners, two tube-mills, Pachuca agitating vats, and other cyaniding equipment. The Casados mine, in the same district, is one of the old Spanish properties that was operated profitably during an early period. In 1907 W. R. Ramsdell and associates took it over and unwatered it, finding the great body of ore indicated by reports of former operators. After installing hoisting machinery a shaft was sunk to a depth of 200 ft., and from it the vein was opened, showing ore that assayed 700 to 1500 gm. silver and 4 to 12 gm. gold per ton. One cross-cut revealed an orebody 15 ft. wide. Plans for a mill are being considered. The work is under direction of T. N. Stanton.

C. D. Dubois and M. E. Schaef, of the Copper Range Co., expect to install a 60-ton copper-matting furnace at their mine, 40 miles from Navidad bay, where they have copper ore, carrying silver and lead. Their equipment is said to be at Guaymas.

JOHANNESBURG, TRANSVAAL.

Classification for Tube-Milling. — Crown Mines. — Cyanide Tailing for Mine Filling. — Labor in 1908. — Rand Statistics. — One Million Sterling Profit from One Mill.

Significant experiments, on a working scale, have recently been made at the Simmer & Jack Proprietary in connection with the classification of tailing pulp for tube-milling. The work has been carried on under the direction of W. A. Caldecott and G. O. Smart, and the results were described by the former at the last meeting of the South African Association of Engineers (a body now gaining in vitality by the broadening of its sphere of activity). Briefly stated, the scheme is to install, instead of the usual spitzlutte and de-waterer, a single conical classifier, yielding, through a large underflow opening (2% in. diam.), a coarse sand product for tube-milling and a peripheral overflow suitable for the sand and slime-plant. A special feature of the conical classifier consists of an internal, notched horizontal disc diaphragm near the bottom, by means of which it is possible to insure a steady underflow of thick pulp, with less than 30% moisture, requiring to be thinned down for the tube-mill feed. One of these classifiers, 6 ft. diam. and 9 ft. deep, has been yielding an underflow of 440 tons (solids) of which 65% remained on a 60-mesh screen (0.01 in.), and an overflow (for the cyanide works) containing 10% coarser than 60-mesh. This could be reduced if the mill requirements were not so heavy. One advantage claimed is the lessened elevation of pulp for the tube-mill circuit; beyond the height necessary to serve the tube-mills, only the final pump being elevated to the classi-

fers for the cyanide works. Other advantages are economy in initial cost; simplicity of operation; dispensing with a supply of mill-water and its pumping-cost; and freedom from liability to derangement by choking, owing to the large size of the underflow outlet.

The basis of the great West Central Rand mine consolidation, for some time foreshadowed, was officially proposed by S. Evans at the meeting of the Crown Reef last week. The new combination, to be named the Crown Mines, will constitute the most productive and profitable gold producing company in the world. It will include the Crown Reef, Crown Deep, Langlaagte Deep, Robinson Central Deep, and the inactive Paarl Central. The Crown Mines, representing an area of 2722 acres of unexhausted reef-bearing ground, and over 5000 acres of freehold ground, will be in a position, if the scheme be carried, to crush 1,800,000 tons of ore per annum. Assuming the yield at 30s., and the costs at 15s., which are justified by present individual performances, the output will approximate £2,700,000, and the profit £1,350,000 per annum. Whatever criticisms may be advanced against other combinations, this merging of interests has in its favor certain factors of relative position that place it above opposition. The chairman, however, made use of the occasion to indicate the advantages of consolidations in general, only lightly touching upon that most apparent in the financial world, namely, the extension of the life of companies approaching exhaustion, and the consequent satisfaction of those shareholders insufficiently acquainted with gold mining conditions to lay aside money from their dividends for the redemption of capital. The principal points of advantage indicated by Mr. Evans were that a company treating large quantities of ore derives more benefit per ton treated from its capital expenditure; that with big tonnages general charges, per ton, are of course reduced to a minimum; that lowered costs enable the great masses of low-grade ore to be treated profitably; that greater concentration of work underground is practicable; and that large organizations can afford to secure the services of the most expert and highly paid men. In this connection, reference was made to the opinions expressed by the Industrial Commission of the United States in 1902 as to the ability of great industrial organizations to secure talent of the highest order.

One of the mines on the Rand, that will soon be extensively re-opening old upper-level workings with a view to extracting low-grade ore from the Main Reef still left in the foot-wall, is arranging for the use of the cyanide tailing as mine-filling. Although tens of millions of tons of this tailing is dumped along the Rand, the material has only been utilized for such a purpose once or twice, many years ago. Its possibilities, however, have often been discussed in view of certain cavings of old ground. In Western Australia, where conditions demand the employment of filter-press tailing in current workings, the Mine Regulations specify that the tailing used shall not contain more cyanide than equivalent to 0.01% KCy, a condition easily obtained by water washing in filters, which is not done on the Rand. It is also stipulated that a strong current of air shall be maintained through any workings which are being filled with such tailing so long as men are working and passing therein. No clause in the Transvaal Regulations refers to the matter, nor will there be any call for legal provisions, as the work is undertaken under the direction of technical men of the highest ability.

Upon reviewing the records for the closing year, it is apparent that the labor position has improved remarkably, and that the ill-effects of Chinese repatriation have been reduced by exceptional increases in the number of Kaffir recruits. Comparisons for January, June, and October stand as follows:

	Whites.	Kaffirs.	Chinese.
January	19,392	153,876	33,849
June	19,985	170,513	19,071
October	20,924	178,367	14,314
Ten months increase	1,532	24,491	19,535 decrease

The net increase in unskilled laborers (excluding the white men now employed as such) is thus about 5000. The ratio of whites to colored workers has remained at approximately 1 to 10.5.

The annual report of the Consolidated Gold Fields of S. A. Ltd. is always of general industrial interest. Indeed, the complaint is sometimes heard that too much attention is devoted to generalities, and too little to matters of special concern to the Corporation's shareholders. One feature worthy of attention is the segregation given of the Rand gold output, giving the year ended June 30, 1908, which shows that the yield of £28,508,368 was accounted for as follows:

	Per cent.
To workings costs.....£16,600,000	58.2
To dividends 8,000,000	28.1
To profits tax 740,000	2.6
To reserve fund, debenture redemption and interest, capital expenditure, etc..... 3,168,368	11.1
£28,508,368	100.0

Further the total working expenditure is divided into the following items:

	Per cent.
White wages £5,650,000	34.0
Colored and Chinese wages... 3,400,000	20.5
Stores 6,300,000	38.0
Sundries 1,250,000	7.5
£16,600,000	100.0

As the colored and Chinese outnumber the white employees by about 10 to 1, the aggregate wages of the two

in output during the ensuing year, there is hope that the round million will be reached. Those who may have been misled by labor-platform utterances as to the omniscience of the capitalist in the Transvaal since the war may ponder the startling fact that the Robinson mine, under the Profits Tax instituted in 1902 by the new régime, will be called upon to contribute about \$500,000 this year to the Colonial exchequer.

NEW YORK.

Mining Share Market. — Wash-Sales. — Copper Stocks. — Lake Superior Corporation.

During 1908 few new mines were promoted in New York, and well-established mining companies found it difficult to finance their operations. In fact, mining stock could generally be sold only at a discount. The New York Stock Exchange report states that the total number of shares traded in on the Exchange in 1908 amounted to 197,003,415, as compared to 196,438,824 in 1907. Not many mining shares are listed on the Exchange, and therefore few such stocks are included in the above figures. In New York, mining shares are chiefly traded in on the Curb Market, but the Curb Market simply reflects the operations on the Exchange. Although the total transactions in 1908 were larger than in the preceding year, it must be remembered that the operations were so abnormal that the State Government has been induced to inquire into the business methods of the Exchange. It appears that a certain powerful financial clique took advantage of the panic in 1907, and with the aid of money loaned by the United States Treasury, made enormous purchases of shares. These shares were carried over 1908 while the prices were rapidly advanced. As a consequence, it is impossible to doubt that the Exchange's statistics include a large number of wash-sales made with the view to advancing prices. It appears probable that efforts will soon be made to unload these holdings. This will absorb a large amount of available capital, and divert attention from mining finance. When, however, the public subscribes to the syndicate's holdings, and to certain railroad bonds, there will be a renewal of interest in mining. Such a revival may occur early next summer, and Nevada gold stocks will apparently be the first to respond.

The copper market continues in an apathetic state. It is claimed that copper production is nearly 30% in excess of consumption. In the last two years many new copper mines have been developed, and the metallurgical plants at most of the large producers have been greatly enlarged. Copper stocks now on hand in the United States are estimated at 70,000,000 lb., and in Europe, at 175,000,000. It would require an exceptionally rapid revival of business throughout the world to create a demand for copper sufficient to absorb the stocks on hand, and take current deliveries.

It is announced that Dennis Sheedy, of Denver, has resigned as one of the directors of the American Smelting & Refining Co. The board now includes five of the Guggenheim brothers, and several of the other directors are employees nominated by them. There has been talk of a compromise between the A. S. & R. Co. and the new International Smelting & Refining Co., but there is no warrant for the story. It is stated that the new company has closed contracts for a large amount of business, and some of it at the expense of the old company, whose Garfield plant has not been entirely a success and will have active competition from the new smelter now building in Utah. Much of this talk simply reflects partisan feeling and an effort to influence the stock market, in fact, the weakest feature in the position of the Guggenheims is their participation in the gambling on Wall Street. In this respect they have played the game like stock-jobbers rather than smelter managers, losing some of their reputation for conservative finance.

An English syndicate has purchased the properties of the Lake Superior Corporation and proposes to develop them on an extensive scale. The properties included in the sale are: the Ontario Lake Superior Co., Algoma Central & Hudson R. R. Co., Algoma Commercial Co., Algoma Iron Works,

Map of the African Goldfields.

classes indicate strikingly the significance of the distinction between skilled and unskilled labor on these fields, though allowance must be made for the free support of the Kaffirs and Chinamen.

The Robinson G. M. Co. bids fair to establish a brilliant record in the annals of Rand mining by declaring profits for a single year amounting to £1,000,000. At the present rate, this mine, with its single mill, should have recorded £990,000 by the end of 1908, but as the gold reserve has been increased to an extent warranting a substantial withdrawal in December, without causing risk of falling short

Algoma Steel Co., Lake Superior Power Co., and many subsidiary companies operating iron, copper, nickel, silver, coal, and other mines. The sale was negotiated through Robert Fleming, of London.

Owing to the unfavorable conditions of the zinc and lead markets, the directors of the Continental Zinc Co. have decided not to declare any dividend for the past quarter.

CHICAGO.

Zinc Smelting at Coal-Mine Mouth. — Sulphuric Acid Production. — Metallurgical Differences Between Eastern and Western Zinc Ore. — Producer Gas in Metallurgy. — Mine Accidents. — Illinois Oil.

Zinc smelting in the Illinois coalfield continues to increase. Within the year just closed two new plants have gone into operation, and another, that of the Mineral Point Zinc Co., at Depue, has settled down to regular work. The plant of the Hegeler Brothers at Danville has been in process of building three years, and into it has gone the accumulated experience of generations of zinc smelters. It is excellent all the way from the mechanical roasters to the warehouses and the workingmen's cottages. Sulphuric acid is made as a by-product, lead chambers being used. At Depue, on the other hand, the contact process was installed, but dust is said to cause difficulty with this process where acid is made from the fume of zinc ore. It clogs the contact-mass and stops the circulation. Except at the original works at Mineral Point, Wisconsin, contact plants seem not to have done as well as the old lead-chambers in this industry.

At Danville the acid made is sold to the United Zinc & Chemical Co., which found itself unable this year to supply the demands from its works alone. The story is that at the beginning of the recent depression the manufacturing department of this concern found the sales department had not kept pace with the growing output of the Kansas plant. A protest was entered and the sales department, being put on its mettle, despite the business depression, promptly made more contracts than the manufacturing department could care for. The result was that the new plant of Hegeler Brothers was called on to help. This seems to show that last year there was business enough for those who went after it.

The new plant of the United Zinc & Chemical Co. at Springfield, Illinois, was erected by R. G. Hall, the superintendent, in record time, namely, approximately four months. No acid is made here as yet, though eventually an acid department will be added. The plant is closely modeled after that in Kansas, owned by the same company, and is run on Western ores, mainly from the Iron-Silver and Yak mines at Leadville. It is an interesting commentary on the skill of American zinc smelter-men that ores containing 14 to 17% iron are regularly charged, and still the retorts, made of the St. Louis fire-clay, and not hydraulically pressed, have a life of approximately 40 days. A few years ago such a result was considered entirely impossible, and probably would be still with Mississippi valley ores of the same iron content. Western ores, it seems, reduce at lower temperatures, 2100° as contrasted with 2800° for finishing temperatures with Joplin blende. Indeed, with Western ores the losses occur in the early rather than the later stages of the process. All this makes to the advantage of the coalfields. Costs at the smaller Springfield plant with producer gas made from cheap screenings, are said to be approximately the same as at the larger Kansas plant using natural gas. The higher thermal efficiency of natural gas, especially where used with regenerators, is not always economical, since it produces an intense local heat and causes high loss of retorts. This, by the way, is the same difficulty which has so far been found when attempts have been made to burn powdered coal under boilers; witness the work some years ago at the Twenty-sixth street plant of the Illinois Central railroad. In the long run the larger use of producer gas in metallurgical operations seems assured, and we may expect more and more smelting to be done in these coalfields, half way between mines and mar-

kets, when by-products will have a larger value due to greater density of population.

In that connection it may be noted that the Illinois Central is now considering the possibility of by-product ovens to coke Illinois coal and to furnish fuel for the engines on the Chicago division. This appeals to them as cheaper and simpler than electrification of terminals to abolish the smoke- nuisance. It has the advantage, to the railway, over central stations and electrical transmission from the coalfields, that it still gets the freight; and railways hesitate to decrease freight; even now this is true of this particular line, although it is short of motive power for handling the freight at present available.

Herman Justl, Commissioner of Labor for the Illinois Coal Operators' Association, and the pioneer among such commissioners, died suddenly at his home in Oak Park on January 1. He was a Kentuckian and a man of many excellent qualities. His part in the general movement toward collective bargaining and trade conciliation was notable and he will be widely missed. In December Patrick McBryde, who held a similar position in Ohio, also died, and M. D. Ratchford has just been appointed to his place. Both McBryde and Ratchford were among the early organizers of the United Mine Workers, while Justl was an attorney and not a laboring man. The large number of labor union officials who have become commissioners for the operators is noteworthy, and they seem to have been uniformly successful. W. D. Ryan, the retiring general secretary of the organization, is shortly to be made Commissioner of the Southwestern Operators' Association. At the annual meeting of the Illinois Coal Operators' Association on January 15, A. J. Moorshead, president of the Madison Coal Corporation, was elected president, and E. T. Bent, of the Oglesby Coal Co., secretary for the ensuing year. It is understood that no change of policy is contemplated. A strong legislative committee was selected and an effort will be made to secure a revision of the mining laws.

Accidents in the mines continue to happen. The Ziegler mine blew up again on Saturday, this time killing 26 men. The fire which caught in the mine in November had just been stopped off and work was to have been resumed Monday. The mine is sealed again to prevent fire, and all the work evidently will have to be done over. The Spring Valley mine No. 2, with its steel and stone bottom and steel top-works was supposed to be fire-proof, but it caught fire December 31 and was wrecked. The fire spread from the stables to the shaft and burned enough cribbing, above the bottom, to cause the tippie to fall; it collapsed as a tangled mass of steel beams. The loss, if the shaft can be recovered, will be approximately \$50,000, otherwise it will be nearer a quarter of a million.

Despite the business depression and the intimate relations of the brick industry to building booms, the year seems not to have been a bad one for the brick-makers, Chicago brick ruled at about \$5 per thousand, and one large out-of-town manufacturer got a factory price of only \$3.50. Even at this, however, under right conditions, there is some money in the business, and numerous new enterprises are planned. Murphysboro is to have a paving-brick plant and also a new yard for making builders' brick. L. C. Davis is to start a plant at Jacksonville, and the St. Anne Brick & Tile Co. is planning to run all winter; an unusual thing to do in this field. To offset these, is the fact that the Millsdale Pressed Brick Co. has gone into the hands of a receiver, G. A. Little being appointed.

Final figures for the year's business of the Ohio Oil Co., the local representative of the Standard in the Illinois field, are now available and show pipe-line runs of 31,972,629 bbl. Miscellaneous receipts added 5,952,912 bbl. The output was distributed with extreme regularity throughout the twelve months.

In addition to this production, the 'independents', the Sun, Cornplanter, and Pure Oil companies, the Indian Refining Co., and the Robinson Refining Co., probably handled approximately 2,000,000 bbl., making a grand total for the year of nearly 40,000,000 bbl.

BLUEFIELDS, NICARAGUA.

Piz-piz District.—Siempre Viva Mine.—Gold Developments.—New Plant.—Hydro-Electric Installations.—Copper Discoveries.

An important gold-mining district has been developed in eastern Nicaragua, and numerous milling and electric-power plants are being installed. The region first became known in 1893 when the Siempre Viva mine was examined by Courtenay De Ka'ib in the interest of W. R. Grace & Co., of New York. The report was favorable, but difficulties with the original owners of the property led to the abandonment of the enterprise by W. R. Grace & Co. The mine was worked in a feeble way by the owners, and finally fell into the hands of Samuel Weil of Bluefields. Today it is operated by the Siempre Viva Mining Co., dominated by William Adler, of New Orleans. A 20-stamp mill has been erected, with a disintegrator for soft ore, and a small cyanide plant has been placed in commission. The company treats 2500 tons of ore per month, said to average \$9 per ton. The mill is being enlarged and electric haulage is being introduced in the mine. The manager is R. B. Stanford. The Siempre Viva vein is of great longitudinal extent, being covered by three claims revealing over 4000 ft. of continuous lode with remarkably uniform gold content. The strike of the vein is northeast, the Concordia mine lying southwest and the Constanca northeast of the Siempre Viva. At the Concordia are 10 stamps and a disintegrator, and at the Constanca is also a 10-stamp mill, to which 10 more stamps will be added immediately, and plans for fine grinding for amalgamation are also being made. This property is owned by the Concordia Gold Mines Co., of New York, of which Gustav Henry Schwab, of the North German Lloyd Steamship Co. is president. The manager is W. A. Conley.

The great gold belt of the region, locally called the Veta Madre, parallels the Siempre Viva vein on the southeast side, and extends across country for eight miles. The largest plant of the district is at the Lone Star mine, on the Veta Madre. Here are installed 30 stamps with cyanide equipment. The deposit is from 50 to 150 ft. wide, and the ore is extracted at insignificant cost by quarrying. The mill treats 3000 tons per month of hard quartz ore averaging \$6.50 per ton in gold. The property is owned and operated by Norman McGinniss, of Toronto, Canada, and William Bluett, of Berkeley, California. Farther northeast on the same lode is the Mars mine, yielding similar ore, which is treated in two Huntington mills, 3½ ft. diam. This property is owned by Charles Lobner and H. B. Sherrick, who are now obtaining bids on a 10-stamp mill and cyanide plant. They have installed a 75-kw., 2300-volt, electric-power plant at the great falls on the Piz-piz river, where 15,000 hp. can be developed at any time. An electric plant at the Siempre Viva falls, where 10,000 hp. is available, has for a considerable period supplied power to several mines in the district. On a cross-lode south of the Mars is the Bonanza mine owned by Joe Lapierre. Here 4000 tons of ore per month are treated in 8 Huntington mills. This plant has a cyanide installation, including leaching tanks and equipment for slime treatment by decantation. Mr. Lapierre is putting in a 200-hp. electric-power plant on a tributary of Tunkey creek, and he will soon replace his 3½-ft. Huntington mills with new ones 5 ft. diam. The high-grade mine of the region is the Josefina, where a \$150 ore is being treated in two 3-stamp prospector's mills. The vein is from 2 to 3 ft. wide, the pay-streak being sorted out, and \$10 ore being stored on the dump for future treatment. This mine belongs to Samuel Weil and associates, of Bluefields. About a mile and a half south from the Siempre Viva, on the watershed of the Banbana river, are the Rosa Lee and Colorado mines, owned and operated by N. J. Martin, of Cape Gracias á Dios, Nicaragua. He is erecting an electric transmission line 8000 ft. long, drawing power from the Siempre Viva plant. The equipment on the property consists of a 5-stamp mill at the Colorado mine, and a 3½-ft. Huntington mill at the Rosa Lee.

This mining district lies at the headwaters of the Piz-piz river, an affluent of the Wanks, which important stream empties into the Caribbean sea at Cape Gracias á Dios. The gold belt also extends over the divide into the watershed of the Banbana river, which empties into the Principulca. The latter reaches the Caribbean at the town of the same name in what was until recently the protectorate of Mosquitia, better known as the Mosquito Coast. By river the Piz-piz gold district is nearly 250 miles from Principulca, but the distance in an air-line will not exceed 80 miles. A mineral belt extends along the foothills of the mountains all the way from the Wanks to the Escondido river, 90 miles southward, and valuable mines have been found at Cuicuina on the Principulca river, 20 miles or more from the Siempre Viva mine, and at Walpatara on the Banbana. The Santa Rita mine at the Walpatara rapids was originally opened and successfully worked by W. D. Parker, for gold. It was bought by New York people, and the Santa Rita Mining & Exploration Co. was organized. Development soon revealed a copper vein 30 ft. wide, from which shipping ore of extraordinary grade has been taken. It is under the management of Clarence C. Semple, formerly

Map of Nicaragua.

at Cerro de Pasco, Peru, and a copper smelter will soon be erected under his supervision. Near the Santa Rita, 4 miles from Tunkey, is El Golfo mine, the property of José Arámburu, where a plant containing two 5-ft. Huntington mills is in operation. A tramway 5 miles long has been built from the mine to the Banbana river. At Cuicuina, the La Luz y Los Angeles mine is being opened on a large scale. A mill is being erected consisting of six 5-ft. Huntington mills and a cyanide plant. Gold in this district was originally discovered at Cuicuina in placers, and exploited by Schultz & Son, of Wunta Plantation; some pocket mines in the vicinity have also yielded large sums erratically. The La Luz y Los Angeles now seems about to give renewed importance to the Cuicuina district. Gold has been reported from the Wawa and the Grand rivers, but no large deposits have as yet been proved; the Topaz mines at Rama on the Escondido river, however, have been shipping large amounts of bullion for several years. This property is remarkably situated, being within two miles of tide-water on the river, and only four miles from Rama, at which point fruit steamers from New Orleans touch several times each month. The plant operating at the Topaz mine consists of 20 stamps with a well equipped cyanide annex. It is controlled and managed by H. J. Brown, of New Orleans, and E. Adler & Co., of the same city, are associated in the ownership. A concession for exclusive prospecting privileges in a wide zone at the headwaters of the Principulca river has been granted to Paul Renér, the original owner of the Siempre Viva mine. The concession is for 25 years, renewable under certain conditions for a like period. Mr. Renér has gone to New York seeking capital.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

All chlorates are soluble in water, but for complete solution of the chlorates of mercury, tin, and bismuth, the addition of a little free acid is necessary.

Charcoal absorbs 9.25 times its own volume of oxygen, that is, condenses it in its pores. It is because of this property that charcoal, once ignited, continues to burn without a draft of air until consumed.

Arsenic would not constitute a basis for the profitable operation of a mine unless the ore contained other valuable products. Arsenic is produced in America wholly as a by-product, and its recovery is not profitable.

Centrifugal force is calculated as follows: multiply the square of the number of revolutions per minute by the diameter of the circle in feet, and divide the product by 5217. The quotient is the centrifugal force when the weight of the body is 1. This quotient multiplied by the weight of the body is the centrifugal force required.

Anvil blocks under mortars in stamp-mills were formerly much in use in South Africa, but are now being discarded, as the vibration is greater than when the mortar is anchored directly upon the foundation. When concrete mortar blocks are employed, the concrete is allowed to set three months before the mortar is placed upon it.

Nickel concentrates in matte along with copper, upon being blown in a converter. The iron can be quite completely eliminated by bessemerizing, without occasioning a large loss of nickel. This process is regularly practiced by the Mond Nickel Co., at Victoria Mines, Ontario, which treats nickeliferous pyrrhotite ores carrying chalcopyrite, similar to the ore at Sudbury.

Drift-bolts should be round instead of square, to develop the highest attainable tenacity. The holes in the timber through which a drift-bolt is driven should be 0.875 of the diameter of the bolt, and the hole in the timber into which the bolt is driven should be 0.8125 of the same diameter. These conclusions are based upon recent experiments made by the Sibley College of Engineering of Cornell University.

Calcium sulphate (gypsum) is soluble in water at normal temperatures. Different investigators give the proportions as 1 of gypsum to 361 up to 443 parts of water. The quantity dissolved increases with the temperature. Considerably larger quantities of sulphate of lime remain in a solution in which that salt has been produced by a chemical reaction. The specific gravity of a saturated solution of calcium sulphate at 15° C. is 1.0022.

Stream-tin, or cassiterite, remains in the pan when washing sand or gravel. It is usually black, but it is remarkable for its colors, varying from grayish white to brown, yellow, and red. It is usually opaque, but is sometimes transparent, when it is called 'rosinitin'. The variety known as 'ruby-tin' has a gem-like transparency and depth of wine-red color. Cassiterite in gravel to the extent of 1 lb. per cubic yard would pay for working.

Sulphuric anhydride is the tri-oxide of sulphur (SO_3). Dissolved in water it forms ordinary sulphuric acid. It is produced along with sulphur dioxide (SO_2) in roasting sulphide ores. The latter compound is a permanent gas, while the tri-oxide at ordinary temperatures is a liquid, and at 16° C. becomes a white solid. The white fume forming in the air above the stack of a roasting furnace is mainly SO_3 . The pungent suffocating odor of fume from roasting sulphides is due to the dioxide.

A junior location, the boundaries of which are so placed as to confer extralateral rights, and which includes the apex of a vein, takes precedence, as far as the vein is concerned, over a senior location which does not include the apex of the vein, but underneath the surface of which the vein extends on its dip. The senior location is only entitled to that portion of the vein lying vertically beneath its surface which is not within the extra-lateral rights of locations properly including the apex of the vein. Priority of location is not controlling under such circumstances.

Ion is the name given to the parts into which a molecule splits up in solution. For example, hydrochloric acid dissolved in water ionizes, splitting into H^+ and Cl^- , the signs indicating the electric charges carried by the respective ions. An electrolyte is a compound capable of dissociation into such ions, and conveys electricity only by means of their migration. All metals and hydrogen are electropositive ions. The theory was first stated by Arrhenius in 1884, but the name 'ion' was applied by Faraday many years ago to the components of a substance conducting the electric current in solution.

The boiling test for cement is also called the accelerated test, because it reveals defects that would show themselves only after the lapse of time in concrete or cement mortar. The defect revealed is that of 'overliming', that is, the existence in the cement of an excess of free lime, which would cause expansion and disintegration in time. The test is made by preparing neat cement in the same manner as for making briquettes, and, with a spatula, applying the mortar to a glass plate 4 in. square; the pat is made in the form of a flat cone, 3 in. diam. at base and $\frac{1}{2}$ in. high. It is kept in a 'moist-closet' 24 hours, and then placed in a pan of water; the water is brought to a boil and kept boiling 4 hours. Sound cement should show no tendency to checks or curling of the edges of the pats, and should remain adhesive to the glass, and the best cement retains its normal grayish green color unimpaired.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Engineer as a Financier.

The Editor:

Sir—In your issue of January 9, J. R. Finlay frankly endorses the view that “the engineer’s work is essentially commercial work, and that its value is simply commercial.” Taking the liberty of substituting ‘economic’ for ‘commercial’ in the sentence quoted, the statement is incontrovertible, and the argument is advanced by a definition. The engineer may take an occasional excursion into the domain of pure science, but it is usually done for the sake of bringing back something capable of economic application. Considered as an engineer, he is assuredly working for economic results. If he also undertakes commercial work, within the field of mining, he is engaged in buying and selling. This means trade in mines, and that is a business different in nature from professional work. This distinction Mr. Finlay will undoubtedly accept. By making it, the engineer as engineer is distinguished from the engineer as promoter. Mr. Finlay allies himself with a class of professional men who insist that it is the privilege of a mining engineer to identify himself with the financial side of speculation in mines. This class includes a large number of the foremost men in the profession, whose ability and integrity are above reproach. The MINING AND SCIENTIFIC PRESS has gone on record in approval of such practices as Mr. Finlay advocates. It said (July 18, 1908): “There is no moral wrong in an engineer holding an interest in a property which he has examined; there is not even any moral obligation which would require an honest man to decline contingent fees, granting that he believed his judgment would not be warped by the self-interest at stake;” but it was further declared: “It would certainly bias the minds of the vast majority of men to the point of incapacitating them for accurate examination, critical use of data, and sound justifiable conclusions.” Precisely there lies the crux of the whole matter.

It is necessary for the engineer distinctly to recognize the economic responsibility involved in the proper discharge of his duties. From the initial stages of his apprenticeship, as an incumbent of inferior positions in mines and works, he is learning how to win results measurable by a monetary scale. The constant aim is a reduction of cost per unit of output. As manager, the problem of earning a profit is the motive underlying every administrative act. After such a preparation in the school of experience he may advance to the stage of advisor, assuming responsibility for valuing mines, and forecasting the economic outcome of projected mining ventures. It is concerning the duties of an engineer who has risen to this dignity that the question of professional ethics applies with peculiar force. He stands between

the vendor and the stock-buying public; it is to his ability, integrity, and judgment that the public looks for safety. It was manifestly not intended by T. A. Rickard that “a man’s work as a professional engineer should be quite divorced from his ideas as a business or financial man,” as Mr. Finlay asserts. As far as the investing public is concerned, a purely technical report would be pointless. That is only half of the responsibility the engineer is obliged to assume. Unless he has the qualifications obtained through training and experience to perform both functions, he is unfitted to pose as a consulting engineer.

Mr. Finlay justly observes that “a man with natural bent for financial affairs cannot be kept from making financial ventures by any code of ethics.” It may also be said that an engineer, frankly interested in a mining venture which has achieved success, wins prestige such that the public will follow his lead in financing new ones. This also works counter to the trammels of a code of ethics that would deny to him the advantage of participation in the profits of promoting enterprises. But therein lies the temptation to over-reach. The tendency has always been strong to over-capitalize mining properties; the element of chance has been insisted upon, and the prospective or indicated orebodies have figured too largely in the valuations reached. If the ore developed subsequently confirms a fortunate guess, the prophet is accorded the honor of a seer, and his next forecast is accepted with confidence. The result is to give a successful man opportunity for exceeding the limits warranted by demonstrable fact in his financial recommendations. This opens the way to disproportionate compensation in shares, which the public will readily absorb if the engineer should become afflicted with doubt concerning the ultimate success of the enterprise before the market had been weakened by sharing his scepticism. In this close relation between mining and the stock market exists the peril which reveals that the engineer stands on a different basis from the common speculator. He has a professional responsibility which is apart from and superior to the financial. To speak of a contingent fee in connection with these operations is to overlook the actual character of the relations now largely in vogue; the engineer gets fees, and also a contingent interest. How to sustain the good reputation of the mining engineering profession in the face of abuses growing from these practices is the difficult question. The engineer who abstains from contingent interests and depends upon cash payments for services rendered is undoubtedly in a strong and more distinctly professional position; his judgment would at least be free from the suspicion of personal bias. But, on the other hand, the engineer who chooses to cast his fortune with the enterprise he has helped to promote is in a position to direct its operations and to give to it the advantage of his supervision. A man engaged merely to examine and report is more often eliminated from the future conduct of the business, and another may fail where he might have seen the way to success. It may also be alleged that responsibility for success has a sobering and steadying

effect, and manifestly a man who is not in command can be held to account only for the seaworthiness of the ship. The outcome of a mining venture depends upon much more than the developed mineral, and the conditions for beneficiating the ore. There is accordingly much to be said in favor of a close financial relation between the advisory engineer and the enterprise to which he lends the authority of his name. The character and extent of that relationship, however, should be known. In publicity is found a salutary check upon irresponsible financeering. A law requiring publicity of all details connected with joint-stock company promotion has for some time been upon the statute books of Ontario, and similar laws have been proposed in the United States. It would seem that in this direction may lie a solution of the problem. It would, in fact, necessitate a larger participation in arranging the financial details of a company-flotation than is now enjoyed by the average engineer. Today the stock interest he possesses is too often a mere sop offered in the expectation of proving a stimulant to his rhetoric in the writing of his report. If the details were to be published as a preliminary to solicitation of stock subscriptions, the patent responsibility for both the financial arrangements and the technical facts would place the engineer in a position that would inevitably stimulate the exercise of prudence and conservatism.

COURTENAY DE KALB.

San Francisco, January 11.

Prevention of Fraud in Mining.

The Editor:

Sir—How shall mining frauds be prevented? Evidently there is much interest in the subject; it is right that it should be so, for the matter is important. The problem is a difficult one, and impossible of complete solution in this old gambling joint we call the world. But, putting my head-light on behind, I can see one effort in that direction, made way back of sunrise some twenty years ago, which may be not wholly without interest. It was the organization in Denver of a Mining Stock Exchange, on an unpatented scheme of protection and honesty. As the organizer of it, my gold of enthusiasm was soon transmuted into barren rock. I thought I held four aces and woke up and found I had but one. Preceding the birth of the Exchange for some weeks, the public was prepared for it by editorials in the daily press. With the tremendous daring of empty inexperience I promised that the public should have an honest deal, and I believed it would. That public swallowed the whole thing—bait, hook, and sinker.

The idea underlying its organization was to evolve a successful method of assisting men to get funds to develop prospects that gave unusual promise of value; to have rules such as would give a fair guarantee that funds would be honestly expended; to protect the public from fraudulent deals, and incidentally to furnish a market for the stock of such mining companies as would play fair in accordance with the rules of the game. The belief was that there was an abundance of money ready for mining speculation if people were satisfied of a good chance for

profit and a fair deal. Events proved that the belief was well founded. If the same events also proved that other beliefs were composed of such stuff as dreams are made of, there is consolation to be found in the fact that to be a fool at times is an integral part of things.

The directors who launched the Exchange were among the leading mining and smelting men, financiers, and bankers in Colorado, in whom the public justly had confidence. In listing prospects, only those of unusual merit were selected; those listed under the first board of directors all made good, and are now producing mines. Every company was required to make a monthly report to the Exchange, stating the amount of money received during the month, and its source; salaries, commissions, wages, and all other expenses paid; amount and character of work done, and its results; and plans for future developments. These reports were open to the public. Stock was listed in two classes, one in a mining and the other in a prospecting class. In the latter only stamped treasury stock was good delivery on the Exchange. The first error was made in not providing that the common stock of the prospecting companies should be pooled until the prospect graduated into a mine. The second error was in not making the board of directors self-perpetuating.

The Exchange began business in a small hall, which was so crowded by the public that in a couple of days it moved to the Chamber of Commerce building. Soon that became too small and it moved into the largest hall in Denver. The public bought stocks as if it had gone insane. Exchange memberships which cost \$100 were selling for \$500 in a few days. The cost of listing was raised from \$100, plus the cost of investigating the property offered, to \$500 and cost, and applications to list came by the score. Soon an election for directors resulted in a new board, which changed the rules for monthly reports of companies so that they became a farce. As chairman of the Listing Committee I was constantly in the minority when voting against listing rag-tag and bob-tail holes in the ground, and I quit. The mermaid with so fair a form wound up in a slimy tail. The machine organized to protect the public became an instrument for the public's spoliation. Its members became the witches of old, to whom "fair was foul and foul was fair." The result was foreshadowed from the beginning.

Unless my philosophy is spavined, an exchange could be organized to be like a toy that is so weighted that, no matter how much it falls down, it will come head up, and be conducted so as to deserve and win public confidence, do much to promote honest dealing, be a benefit to that public which is always willing to take a flyer, and benefit honest mining and honest miners.

W. C. WYNKOOP.

San Francisco, December 22.

The executive and sales departments of the Pelton Water Wheel Co. will move on January 25 from the works, at 18th and Harrison St., to the Monadnock Building.

BLACK DIAMOND.

Written for the MINING AND SCIENTIFIC PRESS
By OSCAR H. HERSHEY.

The majority of prospectors are honest, but nearly all deceive themselves as to the contents of their prospects. I first heard of the Black Diamond, in Crescent City, California, as "A new strike of 600-oz. silver ore beyond Big Flat." Subsequently I met one of the owners, who described it as a vein 30 ft. wide extending through 12 claims, and carrying, according to 119 'tests' that had been made by a man who was studying assaying in San Francisco, from \$3.70 to over \$100 gold and silver per ton, a characteristic being the high silver content. This vein was described as at one place associated with a dike 1000 ft. long and 300 ft. wide, itself low-grade ore. Specimens shown were of a heavy black rock with some green malachite stain, which might be possible ore. I was traveling in Del Norte county in search of mines, and this appeared to be just what I was looking for, so I agreed to accompany the owner to see it, he to furnish camping outfit and provisions. On the first day I journeyed leisurely through the red-woods to a ranch on the summit of Bald mountain. The next day I walked on a rough trail 17 miles to Big Flat; on the way I waded the south fork of Smith river, and was also somewhat delayed by the red huckleberries that grew on the serpentine ridges. I was handsomely entertained at Big Flat by the forest guard, who bakes delicious blackberry pies; these pies reconciled me to the necessity of remaining a day to visit a neighboring copper prospect and to await the arrival of the Black Diamond prospector. On the fourth day we followed the old Kelsey trail over two sharp mountains; the prospector was on horseback, but on those rough trails I preferred walking as being somewhat easier, safer, and swifter. We finally arrived at the cabin of a hunter, whom I had been led to believe was a recluse and might be dangerous; but I learned to know him as a very fine man. My companion had depended on this hunter to furnish us a camping outfit and take us up to the Black Diamond. These men tried to treat me well, but unfortunately the bear meat was too old, and I was compelled to dine chiefly on flapjacks and the luscious blackberries that grew abundantly in the enclosure. I was pretty hungry until we met some fresh meat on the summit of the range next day. In the morning we climbed the main Siskiyou range, following the private trail of the hunter; the only incident of the journey was that one of our pack-horses fell over a bluff. We camped that night in a beautiful clump of silver firs, on the edge of a tiny high-mountain meadow. Several times during the night deer approached the camp.

The next day was devoted to an examination of the Black Diamond property, which we reached by laboriously climbing over the rugged crest of the range. Instead of the vein traceable over twelve claims that had been described, I found an immense inclusion of red chert in a volcanic rock. It was originally a part of the Devonian blue bedded cherts that are widely distributed in northwestern Califor-

nia and carry some iron oxide, but are not otherwise notably mineralized except locally. The chert has in many places been greatly broken up by ancient volcanic action, and masses of it isolated in the lavas are common. The Black Diamond inclusion outcrops 800 ft. long and 100 to 300 ft. wide, courses northerly and dips steeply easterly. The heat of the surrounding lava had somewhat altered it and apparently concentrated the iron oxide from a great mass above into the lower part of the inclusion, producing a bright red chert abounding in thin layers heavily impregnated with a black iron mineral, some of which could be recognized in the field as specularite. It is also seamed with quartz, garnet, epidote, and hematite. At one place are traces of chalcopyrite and of malachite-stain in cracks; there are also slight traces of several unusual minerals. But there is no strong source of ordinary vein-action and the minerals present were probably all 'cooked' from the original constituents of the chert. I did not expect this deposit to carry appreciable quantities of gold and silver, but in view of the owner's positive statements I took three samples at places from which had been taken the samples previously assayed. One was cut across 5 ft. of the best mineralized streak; another consisted of many small pieces from the outcrop 75 by 500 ft., and the third from masses blown out by a blast in what was supposed to be the best ore. These three samples were assayed by a well known assayer in San Francisco, whose returns on each were 40c. gold per ton, and no silver. I am convinced that the prospector was honest; there was nothing wrong except a little misunderstanding in a matter of 119 'tests'. Besides illustrating the statement made at the beginning of this article, this Black Diamond story is intended to introduce into the literature of economic geology a rather unusual type of contact metamorphic mineral deposit, a very highly ferruginous chert-inclusion in lava.

Mixed Geography.—In a recent issue of the *Yale Scientific Monthly* is an address on the Mount Morgan mine, delivered by O. M. Colvocoresses to a senior class of metallurgists and mining engineers. The address begins in these words: "The Mount Morgan mine is best reached from Queensland, New South Wales, via Brisbane, Rockhampton, and the famous camp Gympie. Leaving Queensland on the late afternoon express, one arrives at the seaport of Rockhampton, 900 miles distant, in about 40 hours." A good many people, even in other parts of the world, may have been under the impression that it is not necessary to "leave Queensland" to get to our famous Mount Morgan, and that the State of Queensland is not in the State of New South Wales; but Mr. Colvocoresses claims to have been there, and, of course, he ought to know.—*Queensland Government Mining Journal*.

A large clock has recently been erected on the factory of Colgate & Co., in Jersey City, N. J. It has a dial 40 ft. diam., an hour hand 15 ft. long, and a minute hand 20 ft. long. The latter, with its counter-balance, weighs 640 lb. The clock is illuminated at night by 1200 four-candle-power electric lamps.

THE YUKON DITCH.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

(Continued from Page 120.)

The next division of the Yukon ditch is on Ballarat ridge; it includes both flume and pipe construction: **Ballarat.**

		Elevation.
Intake of flume (4 by 6 ft.)		at 2930 ft.
Discharge into pipe		at 2927 ft.
Length of flume, 1100 ft.		
Details of pipe (wooden stave).		
Length, Ft.	Diam., In.	Staves, In.
9,300	42	1 ⁵ / ₈
3,700	42	2 ¹ / ₂
200	42	1 ⁵ / ₈
800	48	1 ⁵ / ₈
Lowest point of pipe		at 2543 ft.
Discharge into flume		at 2769 ft.
Another length of flume, 650 ft.		
Discharge at 2767 ft.		Grade, 0.3%.

On the Ballarat ridge I watched the assembling and construction of the wooden pipe. The staves are cut to the radius arc. The butt strap, 5¹/₄ in. wide, is a piece of band iron ¹/₈ by 1¹/₈ in. and a little longer than the width of a stave, so that the end jams into the next stave when circled by the bands. The rods are of steel. The shoes are made of malleable iron. The staves are made from 3 by 6-in. California redwood stock and planed to shape at the mill. The inside chord is 5 in. and the outside chord 5⁵/₈ in. The pipe has 30 staves to the perimeter; each stave is of 2 by 6-in. (redwood). These are bound in ¹/₂-in. bands of round iron, tightened by means of a shoe and nut. The bands are spaced from 1¹/₈ in. to 10 in. apart, according to the pressure estimated; they come in the form of straight rods, and are bent to shape by being twisted round a turntable; they are then dipped in asphaltum paint, especial care being taken to coat the shoe thoroughly. I do not know whether this was done, but it should be, as the metal forming the shoe on most stave pipe-lines I have observed is lighter than the band, and hence will succumb to the corrosive effects of the weather.

Lepine Ridge.

The wooden stave pipe follows the top of the ridge between Ballarat creek and the watershed of Rock creek. The Ballarat flows into the Twelve-Mile, which enters the Yukon at a point 18 miles below Dawson, while Rock creek joins the Klondike at 15 miles above Dawson.

Intake of flume	at 2752 ft.
2600 ft. of flume at 26 ft. above ground.	
Intake of pipe	at 2746 ft.
Discharge of pipe	at 2638 ft.
14,660 ft. of 49-in. wood pipe.	
11,887 ft. built in 1907, remainder this season.	
Lowest point at 2556 ft. Several sags.	

The flume along Lepine ridge is carried on a trestle until a height of 26 ft. is gained, in order to get the hydrostatic head necessary for the wooden pipe of 49 in. diam., namely, 7 ft. per 1000 ft. A head of 200 ft. is about the practical limit for the wooden staves; beyond that pressure the spacing between

the bands has to be so close that the steel used (in the form of bands) is almost equal to that of a steel pipe. Under excessive pressure the water squeezes the wooden staves against the bands and destroys the life of the pipe. The wooden stave pipe is furnished by the Excelsior Wooden Pipe Co. of San Francisco. The pneumatic tool equipment comes from the Chicago Pneumatic Tool Co.; and the air-compressor from the Clayton Iron Works, Chicago. In building the steel pipe-lines, instead of using the ordinary slip-joints, which are merely driven together with a ram, each joint is riveted to its neighbor, and pneumatic tools are brought into service for this work.

Lepine Creek.

Intake of pipe	at 2632 ft.
Discharge of pipe	at 2118 ft.
Lowest point	at 1282 ft.

Details of pipe:

Length, Ft.	Material.	Diam., In.	Thickness, In.
816	Wood	49	1 ⁵ / ₈
2,160	Steel	47	³ / ₈ to ³ / ₁₆
1,108	Wood	49	1 ⁵ / ₈

In crossing the valley to Lepine creek it was found necessary to sink 11 shafts to receive bents for the support of the pipe-line. The deepest of these shafts was 64 ft.; it was sunk in blue mud and wash, all frozen. The ground was thawed with a steam-point, 4 ft. at each thaw, so that the ground sank 2 ft., or 50% after each operation. The points were spaced 3 to 4 ft. apart. Owing to the batter (2 in 12) allowed for the posts, the deepest shaft was 9 ft. long at top and 29 ft. at the bottom. The bents are made of spruce, cut from trees 45 ft. long, 6 to 8 in. at the small end and 18 to 20 in. at the big end.

The behavior of wooden pipe in the climate of the Yukon is uncertain, for the life of the material is variable, but the cost is one-third that of steel pipe. I am informed that a redwood stave-pipe of 14 in. diam. has been in use at Nome since 1900 and has given satisfaction. The pipe brings water from Moonlight springs to the City of Nome.

Klondike Pipe-Line.

The largest single task on the whole line of construction was the installation of the inverted siphon crossing the valley of the Klondike river. The details of this line are as follows:

Intake	at 2440 ft.
Discharge	at 2240 ft.
Lowest depression	at 1282 ft.

Details of pipe:

Length, Ft.	Material.	Diam., In.	Thickness, In.
760	Wood	49	1 ⁵ / ₈
7,520	Steel	43	⁵ / ₈ and ¹¹ / ₁₆
6,850	Steel	49	¹ / ₄ , ⁵ / ₁₆ , ³ / ₈ , ¹ / ₂ , ⁵ / ₈
1,629	Wood	49	1 ⁵ / ₈

These data give an inadequate idea of the size of this particular undertaking. The Klondike valley is a deep wide depression, and crossing it with an inverted siphon involved the use of three miles of pipe, one mile of which is under a head varying from 1150 to 1000 ft., that is, the line had to be built to sustain a pressure of, approximately, 500 lb. per square inch. The hillsides flanking the valley are steep and this

presented engineering difficulties in the way of anchorage for the heavy pipe, as well as the handling and distribution of the material. Across the Klon-

calculated to a nicety. Practically the total length of the high-pressure portion is lap-welded pipe, furnished for the greater part by Riter & Connelley, of Pittsburg, although purchase of 1400 ft. was made in Germany. Some of the sections of the German lap-welded pipe are 36 ft. long, and weigh over four tons.

The excavation for the pipe-trench, the setting of the foundations, and the final placing and riveting together of the pipe, required the employment of over 300 men for nearly two summers, and the continual supervision of from one to three constructing engineers. The riveting and laying gangs worked day and night throughout the summer season. Five air-compressors, electrically driven, were employed on the work, as this line required to

Removing 'Muck' On Twelve-Mile Face.

dike flats, which overflow each spring, the pipe is supported by a system of pile-bents, each bent being composed of four heavy piles driven into the bed of the stream. In crossing the Klondike the pipe is carried by a three-span steel bridge, each span 95 ft. long, mounted on piers, erected in mid-winter. Each pier is composed of piling surrounded by mortised timber, shod with steel.

The design and manufacture of this pipe involved the employment of engineering talent of the highest class, as practi-

Constructing Stave-Pipes on Lepine Ridge.

Shovel No. 5 in Operation.

cally each section of the pipe, on account of the pressure involved, had to be specially designed, and all of the bends and angles in the lap-welded portions

the lower side, and against the bank thus formed poles are laid close together, the points being placed 2 ft. below the grade of the ditch. Upon the poles is

be caulked both inside and out, as well as riveted. The last rivet was driven and the line completed on October 9, 1908, thereby closing the last gap in the construction of the main ditch system as far as Lovett gulch.

In building the ditch, many natural obstacles were encountered. They were overcome by methods suggested, for the most part, by experience gathered elsewhere in the North. The following examples will prove suggestive:

1. Frozen muck, where there is material for constructing the lower bank—see Fig. 1—is scraped by the aid of horses so as to accumulate on

spread a layer of moss or sod from 6 to 12 in. thick. Then dirt, or other good tamping material, is scraped, forming a slope 5 ft. from the toe of the moss, and inclined at an angle of $1\frac{1}{2}$ to 1.

2. Fine silt or 'glacial' sand, which is frozen material that upon being exposed to the warm air, upon removal of the moss, thaws to a slime (see Fig. 2). In such material the ditch is dug 16 to 18 ft. wide,

during the first season; the lower bank sloughs away; the upper bank melts, and the ditch is practically obliterated; but by maintaining open drains the whole mass is dried. In the second season the ditch is dug again, and the stuff that filled it serves to form the lower bank. Poles, moss, and fill are arranged as in No. 1. When the moss on the upper side is thick and remains unbroken, it drapes the underlying silt, which continues to run out like a thin mud until it finally attains the angle of rest; then the moss protects the bank from further thaw. When, however, the moss of the upper bank is thin or brittle, the silt slides into the cut, and must be scraped by teams to the lower side. In cases where

the lower bank is so uneven that poles cannot be laid regularly, two stringers are stretched longitudinally to serve as a base for the poles. These stringers are held in place by logs placed horizontally underneath the lower bank.

3. Shattered schist (see Fig. 3) is easy to dig, but it makes leaky ground. Digging is done by the steam-shovel and the ditch is made 14 ft. wide at the bottom. The corners are excavated by hand-labor, and filled with moss to a depth of at least 12 in. The bottom of the ditch is also blanketed with a foot of moss. On top of this is spread a covering (8 to 12 in. thick) of good puddling dirt, and the sides are given a slope of $1\frac{1}{2}$ to 1.

4. A rocky slope, with no lower bank (see Fig. 4) offers another problem. On the lower side a crib of logs is built, with a base 6 ft. wide, and a top 4 ft. wide. This framework is filled with broken rock. Moss and puddling are applied as before.

It was no light task to take care of the men engaged in this work; they were scattered over a line reaching more than 50 miles from Dawson, the various camps being pitched in a wilderness of scrub and soggy moss. No supplies, either of food or material, are hauled in summer, for all the roads except those built by the Government near Dawson,

are then impassable by heavy wagons. Hauling is done exclusively in winter. The stumps and brush are cleared in a line across the marsh and as soon as the frost comes a passage is effected. A plow removes any excess of snow, and the road is watered so as to give it a durable crust of ice. Logging-sleds from Michigan are used; the average load is 9 tons with 4 horses, and 11 tons with 6 horses. The maximum load is 15 tons, with 6 horses. It cost \$2000 to set up a camp, and it cost \$7000 to \$12,000 to get a steam-shovel ready to work. Not less than \$75,000 worth of horses were employed, the price at Dawson being \$800 to \$900 per pair.

The magnitude of the work accomplished by the engineers of the Yukon Gold Co. may be inferred from an enumeration of the tasks completed during the three seasons since the first surveys were finished: 7 dredges in commission; 3 mechanical elevators; a dam and reservoir (700 miner's inches for 40 days) on Bonanza creek, connecting ditches, flume,

and pipe (aggregating 9 miles); a power-plant of 2000 hp., with 36 miles of main line, 18 miles of branch, and 8 miles of secondary lines; 64 miles of main ditch, flume, and pipe of 5000 in. capacity. All this has been done 3500 miles distant from manufacturing centres, with an inadequate supply of labor. Some of the machinery that arrived at the time of my visit had been ordered 18 months previously. The company was carrying 1812 men on its pay-roll, representing from 1600 to 1700 men continuously engaged. This called for an expenditure of \$300,000 per month. In the examination of the claims purchased or optioned not less than \$55,000 was spent.

During the season of 1907 over 7000 tons of material was received, and it was inevitable that some of the parts ordered in advance, for immediate operations, should be delayed in delivery despite every effort. It is always difficult to operate when also engaged in construction work on a large scale. Moreover, some of the work was experimental, and the charges for this had to be absorbed concurrently with the capital expenditures. Of the 4 large dredges, 2 are of Bucyrus and 2 are of Marion manufacture, each couple being of the same pattern, so that the parts are interchangeable. The 3 smaller dredges are of identical design, and entirely interchangeable. A sufficient stock of parts is carried, so as to obviate

Discharge End of Pipe on the Little Twelve-Mile Creek.

Finished Ditch, Before Water is Admitted.

delays from slowness of transport. Maintenance of a proper commissariat for laborers scattered over an area 70 miles long by 30 miles wide, required some generalship. Laborers get \$4 per diem and board, the latter costing the company from \$1.75 to \$2. An effort was made to overcome the uncertain supply of local labor by importing 320 men from British Columbia. Of these 20 deserted on the way. Owing to the shortness of the season, to the expense of travel, and to the opportunities for individual mining, it is difficult to keep intact a force adequate for so large an engineering work.

The supervision has been in the heads and hands of young men, mostly graduates from mining schools. The chief, O. B. Perry, is a graduate of the Columbia School of Mines; the resident manager, Chester A. Thomas, hails from Stanford University; the superintendent of dredges, E. E. McCarthy, is a Harvard man; the head of the hydraulic mining, George T. Coffey, is a graduate from the school of experience. Berkeley contributes two or three good men, but for obvious reasons Stanford is more largely represented; for example, H. H. Hall and E. A. Austin hail from Stanford. Most of these men range between 25 and 33 years of age, with a few youngsters, but it was noticeable that even the chiefs of divisions were not much over 30. They constitute a fine body of young and vigorous men, willing to make the most of the long Arctic day, and eager to hasten a work of which it can be said that it is the most interesting example of man's invasion of the trackless wilderness that borders the Arctic Circle.

NEVADA'S METALLIC WEALTH.

The mines of Nevada produced in 1907 gold, silver, copper, lead, and zinc to a total value of \$17,591,486, according to final revised figures in a report by Charles G. Yale, just issued by the United States Geological Survey. The yield of gold alone was 585,311 fine ounces, valued at \$12,099,455; and of the silver, at the average commercial price for the year, \$4,675,178. The combined increase was \$1,767,619.

There was an increase in tonnage of all kinds of ore mined. Out of a total of 723,581 tons, 628,501 tons were silicious ore, of which Nye county produced 241,677 tons, and Tonopah 214,357 tons. The average value per ton of silicious ore in gold and silver was \$25; of copper ores, \$6.65; of lead ores, \$9.86; of copper-lead ores, \$16.87; of copper-lead-zinc ores, \$25.81; and the average value per ton of all kinds of ore was \$23.10. During 1907 the gold and silver mills treated 436,779 tons of ore, from which were saved \$2,785,634 in gold, or an average per ton of \$6.38, and \$1,400,039 in silver, or an average per ton of \$3.20; a total value in gold and silver of \$4,185,673 and an average per ton of \$9.58. From 436,779 tons treated at gold and silver mills, and from 16,569 tons of copper, lead, and zinc ores sent to concentrating mills, a total to both classes of mills of 453,348 tons, 11,702 tons of concentrate was produced, valued at \$445,642 in gold, or an average per ton of \$38.08, and at \$739,226 in silver, or an average per ton of \$63.17, a total in gold and silver of \$1,184,868, and an average of \$101.25.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination.

W. E. H., Pioche, Nevada: Volcanic rock—basic andesite or basalt.

H. W., Burrough, California: Pyrite and chalcopyrite in mica schist.

W. L., Silver Peak, Nevada: No. 1, impure calcite with flakes of graphite too small for satisfactory proof; No. 2, gypsum.

J. H. P., Golconda, Nevada: No. 8, shaly rock with much kaolin and some pyrite; No. 9, shale, much weathered and charged with limonite.

C. W., Wadsworth, Nevada: No. 1, gypsum in a rock highly charged with limonite and containing minute traces of some undeterminable sulphide; No. 2, rock highly charged with limonite of unusually light yellow color.

J. Q. McG., Coldfoot, Alaska: Miscellaneous pebbles, quartz, manganese oxide, etc., with nuggets of white metal which exhibit the cleavage of native bismuth splendidly and give blowpipe reactions for that metal. A careful search failed to detect other elements present in these nuggets, which, therefore, are native bismuth.

R. B., Goldfield, Nevada: No. 1, granular quartz aggregate with limonite, kaolin, and small specks of iron pyrite; No. 2, pyrite in sheared quartz rock, of very fine grain, containing some kaolin; No. 3, abundant limonite and some pyrite in impure quartz rock; No. 4, mica schist (biotite mica); No. 5, granular quartz with some muscovite; No. 6, quartzose shale; No. 7, an aggregate of pyrrhotite in quartz, with chlorite and talc.

F. E. H., Coldfoot, Alaska: These metallic nuggets show the cleavage of native bismuth and give blowpipe reactions for bismuth only. The substance is completely volatile before the blowpipe. No indication of lead, sulphur, antimony, or arsenic was obtained. If elements other than bismuth are present they are not in sufficient quantity to be detected by ordinary blowpipe tests. Some of the nuggets have a fused appearance, as though melted before being sent in for determination.

J. H. P., Golconda, Nevada: No. 1, an aggregate of limonite and kaolin with mica and quartz in small amount; No. 2, an aggregate of kaolin, quartz, and limonite, possibly a weathered rhyolite or rhyolitic tuff; No. 3, hematite in quartz rock; No. 4, shale; No. 5, shale, much sheared, almost schistose; No. 6, a sheared quartzose shale, probably, with pyrite in elongate cubes. This development of pyrite resembles millerite but no indication of nickel was obtained. No chlorite could be determined definitely. No. 7, impure quartzite, traversed by quartz veins; No. 8, quartzite.

GOLD REGION OF THE STRAIT OF MAGELLAN.

By R. A. F. PENROSE, Jr.

*The Strait of Magellan intersects the southern end of South America from east to west. To the north is Patagonia, and to the south is the archipelago of Tierra del Fuego. Both these regions are owned partly by Chile and partly by the Argentine Republic. The Chilean possessions in the Magellan region, on both sides of the strait, are officially known as the Territory of Magallanes, a term locally abbreviated to 'Magallanes'. Patagonia represents the southern end of the mainland of South America, terminating at Cape Froward, in the Strait of Magellan. The name of Tierra del Fuego properly belongs to the whole archipelago of islands lying south of the Strait of Magellan and north of Cape Horn. It comprises an area extending about 500 miles from northwest to southeast and about 200 miles wide. The two main tidewater channels are the Strait of Magellan on the north and Beagle Channel near the southern part, intersecting the region from east to west. There are numerous other minor and transverse channels, dividing the archipelago into many islands. South of the Strait of Magellan, in Tierra del Fuego, the western and southern parts of the archipelago are rugged and mountainous, some of the peaks rising from 3000 to 7000 ft. above the sea. This region represents the southern extension of the Andes, which here turn to a southeast course, and then to an east-and-west course, finally terminating in the rugged Staten island, the most easterly member of the archipelago. The northeastern part of the main island, however, is a more or less flat or rolling country, and partakes of the nature of the pampas of eastern Patagonia. Tierra del Fuego probably owes its condition as a group of islands to a partial submergence of the southern end of South America. The islands appear to be the upper parts of old mountain peaks, and the numerous straits, channels, and bays mark the courses of the old canyons and valleys. The rocks of southern Patagonia and Tierra del Fuego have not been much studied, but it may be said that they are mainly granites, various igneous rocks, and slates; while in the low pampas country in eastern Patagonia and the northeast part of the main island of Tierra del Fuego soft, sandy, and argillaceous strata predominate, probably Mesozoic and Cenozoic.

Gold is said to have been discovered in southern Patagonia by the Chileans over 40 years ago, and is supposed to have been known to the native Indians at a much earlier date, but it has been produced in quantities sufficient to attract general attention only in the last twenty years. The gold in the gravel of Rio de las Minas, near Punta Arenas, was one of the earliest discoveries. Another was the gold in the beach sands near Cape Virgins, at the eastern entrance of the Strait of Magellan, discovered about 1876, but not actively worked until 1884. An Austrian named Julius Popper was among the most active operators at that time, especially on the east coast of the main island of Tierra del Fuego. Gold

was actively worked on both sides of the Strait of Magellan, but the principal localities were the gravels in the Rio de las Minas near Punta Arenas, the beaches at Cape Virgins, and from there southwestward along the shore to Point Dungeness; the gravels on several small streams to the eastward of Porvenir, across the strait from Punta Arenas; the beach at Paramo northeast of San Sebastian bay, on the east coast of the main island of Tierra del Fuego; Navarin island, Lennox island, New island, and Sloggett bay in the extreme southern part of the archipelago near Cape Horn; New Year island, which lies north of Staten island, at the eastern end of the archipelago; and several localities in the western islands of the archipelago. In fact, gold has been found generally distributed through the Magellan region.

About the year 1904 preparations to use steam dredges started the boom afresh. From all over Chile and Argentine again came the gold-seekers, with some from a still greater distance, and the usually almost deserted Strait of Magellan became animated with small craft. Since that time work on the gold deposits has steadily progressed, in a much more systematic manner than formerly. In 1907 some twelve dredges were in operation or being constructed, and the gold industry of the region promises soon to become important. The most active man in introducing dredges has been an American, John D. Roberts. The dredges are not used in handling the beach deposits, as the fury of the storms would soon batter them to pieces; their use has so far been confined to the inland deposits.

Until recently the largest gold-mining operations were at Paramo and Lennox island, but since the introduction of the dredges, the most active operations are on the northwestern part of the main island of Tierra del Fuego, across the strait from Punta Arenas. Here the town of Porvenir is the headquarters of the industry. This town is now a prosperous mining centre of about 800 people. In addition to the Porvenir region, mining on a small scale, but of more or less importance, is still going on at some of the other localities.

The chief centre of civilization in the whole region is the Chilean town of Punta Arenas, a name which in English means Sandy Point. The town is on the Patagonian side of the Strait of Magellan and has a fairly good harbor. It is the seat of government in this part of the Chilean possessions and is an active place of 12,000 population. The settlement of Ushuwaia, which is the seat of government of the Argentine part of Tierra del Fuego, is only a small place. Punta Arenas is in 53° 9' 42" south latitude, and has the distinction of being the most southerly town of any considerable size in the southern hemisphere.

Punta Arenas was started by the Chilean Government as a penal colony in 1843. The Chilean Government finally ceased using it as a penal colony and encouraged its settlement by free Chileans. For a long time it was the headquarters for sealing and whaling vessels, until the seals and whales became nearly exterminated. In recent years Punta Arenas has prospered, first by the development of the sheep

*Abstract from paper in *Journal of Geology*.

industry in Patagonia and later by the advent of the gold miner.

The gold of the Magellan region is, so far as at present known, most all in alluvial deposits. Very few gold-bearing veins have been found. The alluvial deposits may be divided into two classes, those in beds of creeks or on hillsides, and those on sea beaches where they are subject to the action of the sea during the falling tides and during storms. The alluvial deposits in beds of streams or on hillsides vary in gold content from a few cents to \$1 or more per cubic yard, but most of the ground that is now worked is said to range from 25 to 50c. per yard. Under the conditions existing in the region, it is difficult to make low-grade ground pay, but some of the operators expect, with steam dredges, to make a profit on low-grade ground. The gold-bearing beds vary from a few feet to 10 to 30 ft. An overburden of barren ground often occurs.

The gold on the beaches is sometimes on the immediate surface and sometimes covered by from a few inches to several feet of barren sand. On some beaches it is well up on the shore, on others it is near the water-level, and on still others it is below the water-level. The sandy strata carrying the gold are rarely over a few inches thick, but often rich. The gold is associated with large quantities of black sand, which seems to be mostly magnetite; there are also numerous small garnets. The gold, whether from the creeks, hillsides, or beaches, is said to be quite pure, though it often contains a little copper and silver. It occurs generally in rather fine particles, but sometimes small nuggets, often flat and about the size of lima beans, occur, and occasionally still larger ones are found, but no great nuggets have yet been discovered. The gold in the beaches probably came largely from the later erosion of the alluvium in the creek beds and on the hillsides, and perhaps partly from old submerged alluvium, from which the gold was thrown up by the sea. It is said that the beaches, after having been carefully worked for gold, seem again to become rich in that metal after a storm or an unusually high tide. A similar phenomenon is observable in the gold-bearing beach sands of Cape Nome, Alaska. The ordinary tides in the eastern part of the Strait of Magellan have a rise and fall of 30 ft., and the spring tide, 45 to 50 ft., though in the western part of the strait the tides have a much less rise and fall. The great rise and fall of the tides on the Atlantic side cause rapid currents in the strait, often with a velocity of 7 or 8 knots per hour, and these, scouring the beaches backward and forward, must have a marked effect in concentrating the gold. In fact, the conditions in the Strait of Magellan represent a natural process of concentration, not at all unlike some of the artificial processes that man has found best suited for concentrating gold.

Prospecting in the Strait of Magellan and Tierra del Fuego is a more difficult task than in most places, and many a man has lost his life in his search for gold in that bleak, inhospitable region. Traveling is mostly done in boats, as the land is much cut up by deep tidewater channels and bays, and covered with dense underbrush or immense peat bogs; while every-

where, even on the mountain sides, the soil is soft and boggy, so that walking is difficult and often impossible. The climate, however, though stormy, is not extreme, the thermometer rarely going much below zero or much above 60° Fahrenheit. The mean winter temperature is about 33° F. and the mean summer temperature about 50° F. The season during which mining can profitably be carried on is from August to May. During the rest of the year frost and snow hinder operations. The capital at present invested in the industry is mostly Chilean and Argentine.

MEXICO'S MINERAL OUTPUT.

The annual budget sent to the Mexican Congress by Minister of Finance Limantour on December 14 gives some interesting figures as to the mineral output of the Republic. For 1907-08 the production was as follows:

Gold	₱ 38,096,000
Silver	85,447,000
Copper	24,800,000
Lead	5,400,000
Zinc	900,000
Other metals	2,500,000
Coal	7,000,000
Mineral oil	2,000,000
Total	₱166,143,000

Gold ore and bullion exports, minus Mexican and foreign gold coins exported, were 20,156 kilograms, or ₱26,874,705; gold purchased for coinage by the Exchange and Currency Commission, less ₱2,563,857 obtained from foreign gold melted down, 8316 kg., or ₱11,088,622; home consumption, 100 kg., or ₱133,333. The total production of gold for 1907 is 828,572 kg., amounting to ₱38,096,661, and for the year previous, 27,423 kg., or ₱36,563,898, an increase of 1149 kg., or ₱1,523,763. The exports of silver, minus those of Mexican and foreign silver coins, for the same time were 2,065,510 kg., valued at ₱82,192,655. Mexican silver bars bought for coinage, 85,504, or ₱3,174,249, with a home consumption of 2000 kg., or ₱80,000. The total production of silver for 1907-08 was 2,153,014 kg., valued at ₱85,446,904, while that of 1906-07 was 1,756,704 kg., or ₱77,088,877, an increase of 396,310 kg., or ₱8,358,077. In mineral output Mexico ranks first in silver, second in copper, fourth in lead, and fifth in gold, and, it is said, will establish a high record for this year with 86 of the most important mines owned by Americans. There are large amounts of American capital invested in the railroads, mines, and other industries, and three-fifths of the dividend-paying mines are held by residents of this country. From close figures it is said that the dividends from these will this year be over 25% in excess of the net earnings of all the national banks in this country, which during the fiscal year amounted to \$79,863,898. Those banks, according to figures from the Wall Street Summary, paid only 5.46% earnings to capital and surplus, while some of the mines in Mexico rated as fourth and fifth rate are paying 10 and 15 per cent.

ACETYLENE MINE-LAMPS.

Written for the MINING AND SCIENTIFIC PRESS
By A. CRESSY MORRISON.

For several years acetylene has been used in miners' lamps in France, Germany, and Belgium, until at present it is used almost exclusively in more than 200 mines and by 50,000 men. The light is satisfactory, saves nearly 50% of the cost, giving more and better light. Mining engineers have been familiar with this fact, but the introduction of acetylene into mines, up to the last two years, has been very slow in this country. Its use is now, however, coming to be recognized as an important advance, and it promises shortly to replace all other means of illumination, except in special cases.

It is seldom that an improvement in quality or advantage is accompanied by reduction in cost, but the paradox is a reality in the case of acetylene. Candles, which are largely used in our Western mines, consume 7 times, and kerosene 5 times, as much oxygen as acetylene. The products of combustion given off by candles are 10 times, and from kerosene 9 times, as much as that given off by acetylene. The difference is therefore enormous. While acetylene in a mine gives off no smoke whatever, every miner is familiar with the difficulty due to products of combustion from other illuminants. Acetylene, therefore, makes for the life and comfort of the miners, protects them from the degenerating effects of insufficient oxygen, and removes the one important cause of lung and throat troubles. The actual amount of illumination given by candles and kerosene is lessened by the smoke and mist that so rapidly accumulate, whereas all the light given by acetylene reaches the point to be illuminated, without any interference whatever. It has been found, in actual experience, that in entries which are 60 to 70 ft. ahead of the air, there is not the slightest particle of smoke from an acetylene lamp, and the entry is just as clear at the end of a shift as it is at the beginning.

An interesting thing about acetylene is the tenacity of the flame. It is not easily blown out, the rapid motion of the miner will not cause it to flicker badly, and it burns brilliantly in an atmosphere so foul that candles fade and go out. In fact, acetylene will not deprive the miner of light until the atmosphere is so bad that it will not support life. For underground surveying and mine inspection, the use of acetylene is of great importance. Maps and records escape the usual accompaniment of grease and smudge. The acetylene flame is so small and clear that it affords an accurate point on which to sight instruments.

Another use for acetylene in somewhat larger units is found where the rays are concentrated by a reflector, in which case a brilliant illumination can be thrown into inaccessible places where distant bays, high backs, caved places, and other difficult and otherwise hidden parts of the mine can be explored with convenience and, in case of emergency, without danger. Acetylene is especially advantageous as a cap-lamp for drivers, and it has been found, where

mules are used, that they can see much better and are not nearly so liable to stumble.

The poor quality of oil for mine use has in some States called for laws establishing a standard quality; these laws are frequently violated by a species of adulteration which almost defies detection, affording another powerful argument in favor of the substitution of some illuminant that cannot be adulterated. In this connection, it is interesting to realize that acetylene is made in the mine-lamp as used, the principle being the bringing of water into contact with the carbide as the gas is burned, and in just sufficient quantity. The difficulties of this problem have been overcome. As soon as the pressure of gas reaches the proper point for burning, it holds the water in check until the consumption at the burner has so reduced the pressure that the water comes in contact with the carbide again. In actual practice it has been found that four ounces of calcium carbide at four cents per pound will give nearly 10 candle-power clear illumination, without smoke, for 5 hours. One half-pound, or two cents worth, will give the same illumination for 10 hours. Candles in many parts of the country, counting four candles to the 10-hr. day, would cost five cents per day. There seems, therefore, to be no reason why acetylene should not be introduced, provided a proper lamp at an economical price can be devised. As a matter of fact, practical experience has demonstrated that some of the mine-lamps now upon the market meet all the necessary requirements as to economy, lasting quality, and practicability.

Acetylene mine-lamps are now found in mines throughout the country; Pennsylvania, New Jersey, and Illinois lead in this regard, though many other States are using the new light. The greatest number used by any one concern in its mines is probably by the New Jersey Zinc Co., of New York, which has adopted acetylene illumination throughout. The number of mine-lamps in use in the mines of this company is now about 3000, and it is found that the saving is at least two cents per day for every miner.

The whole method of using acetylene is so simple, and the lamps now in practical use are so satisfactory, that the subject of better illumination in mines is worthy of attention of every mine owner and engineer. It is equally worthy of the attention of every mining organization, as well as every individual miner, because a change to better illumination at half the cost, with the greater output, safety, comfort, and, above all, good health, are matters of such vital importance that no careful manager should fail to investigate the subject.

The Cullinan Diamond, which was presented to King Edward VII by one of the South African states, has been cut into nine stones. In its original form the stone weighed 3025 carats. The two larger stones weigh 516½ and 309½ carats, and are five and three times larger, respectively, than the famous Koh-i noor. Besides, there are 96 brilliants and a quantity of unpolished ends. The big stones have been cut with extra facets and are of remarkable brilliancy.

MILLING COSTS.

Written for the MINING AND SCIENTIFIC PRESS
By R. S. HANDY.

It is not generally good business practice to sell for less than cost, or to guess at profit and loss; and yet it is notorious that these two evils exist in most ore-milling plants in the West; that is, they generally contain some machines that cost more to operate than they produce, and, while the total income from the plant is determined accurately, the profit can only be guessed because the costs are not known.

This condition is not the result of inability to get at the costs, individual or total, in these plants, for they are operated by men at least as able as those who manage commercial or manufacturing enterprises of the same magnitude where close records of cost are kept. Indifference to the fine points of cost and efficiency in the milling of ores can only be explained by the lack of direct competition involving dollars and cents, the nearest thing to it being professional rivalry as to results obtained. If these milling plants had to bid in open competition with other mills for all of their ore, and there was not quite enough ore to go round, there would probably be some radical changes in the records of costs and efficiency in most of them, especially the successful bidders.

If a close margin of profit is conducive to reduced costs and increased efficiency, it can be introduced into any mill by assuming that the ore is bought from the mine on an arbitrary margin, the basis of purchase established being maintained throughout, whether it show loss or gain. For instance, in a certain mill the average experience for the preceding year shows a net profit of 40% of the average gross value of the feed. Then establish as a basis of purchase from the mine, say 38% of the assay-value of the feed on date of delivery to the mill. This will leave a 2% margin of profit under conditions existing for the previous year, and will establish a standard for comparison. But fluctuating conditions will make it interesting to keep the balance on the profit side of the ledger, and the figuring can be made as closely as if the ore were actually being purchased in this way. For example, a lead concentrator treating 1000 tons per day and working under the above assumption with lead at 5c. per pound and silver at 55c. per ounce, would make a profit of about \$2000 per month. With the prices reduced to 4c. per pound and 50c. per ounce, the extraction and operating costs being the same, the result would be a deficit of about \$500 per month. These figures leave a vastly different impression from the customary ones involving gross values of hundreds of thousands of dollars.

With the above assumption for a starter, the following suggestions might be applied for arriving at milling costs and efficiency. They apply, in this case, to a lead-silver concentrator.

1. Get the dry weight of ore milled each day.
2. Arrange the feed-sampling apparatus so that the assay of the feed represents the actual contents of it, rather than an abstract figure on an assay report.

3. Have the spouts carrying the concentrate discharge into a trunk launder for each class of product and let these discharge into their respective bins in such a way as to admit of easy time-sampling.

4. Have time-samples taken hourly of the different classes of concentrate from the above launders and the total sample for 24 hours of each weighed and sampled for moisture and assay in such a way that the least time will elapse between the end of the sampling period and the assay results.

5. Calculate the gross value of the marketable mineral content of the feed and of the product each day at the market rate for that day. The ratio gives the extraction accomplished.

6. Assume a constant as cost for the ore at the mill, say, a certain percentage of the assay-value, as a standard for comparison.

7. Figure the actual profit from shipping the different grades of product in No. 4.

8. Find the net daily profit by subtracting No. 6 from No. 7 and the daily cost of operating from the result.

9. Have each machine in the mill arranged for sampling its feed and products separately by time-sample, if possible.

10. Number each machine and determine the cost of operating it for 24 hours. Place these data on the sheets in the Test Book (See Fig. 2, 3, and 4) described hereafter. Index the Test Book with as many cross-indices as will enable you to turn at once to any given machine.

With the above data in shape you can, with practically the same amount of labor as is now devoted to sampling and assaying grab-samples of tailing and products from which no tangible results can be obtained, get actual results in dollars and cents each day, showing very closely the profit from operations and the efficiency of the plant.

The test-sheets enable you to have a number of tests made each day on individual machines, depending as to number upon the capacity of the assay-office and the sampling force. These tests should be made systematically, but not in regular rotation, so that the operatives, knowing their machines to be next in order, could have them in apple-pie order for the occasion. If these tests were made impartially, regardless of the conditions under which the machine is running, some interesting data could be gathered as to the losses from machines working badly temporarily. These data, I believe, cannot be gathered from 'experience.' The above system would undoubtedly tend to increase the efficiency of millmen.

Referring to Fig. 2, 3, and 4: these are forms for the Test Book, they are suggestions for a lead-silver concentrator and are self-explanatory. No. 2 may be used, by adjusting the details, for crushers, rolls, conveyors, elevators, Huntington mills. No. 3 for jigs, Wilfley tables, vanners, etc. No. 4 for trommels, screens, classifiers, and so forth.

The daily report blank, Fig. 1, follows the suggestions numbered 1 to 8, inclusive, above, and is lined for 31 days, for totals and averages; and lines for comparing the totals and averages with the regular monthly report based on actual shipments.

BROKEN HILL SILVER MINE.

By E. C. ANDREWS.

*Having spent a week at the Broken Hill silver mine, I prepared a short note on the occurrence of ore, of which the following is a summary. Several geological facts become at once apparent. Thus: (1) The Broken Hill area is a mass of crystalline schists and allied rocks, all possibly pre-Cambrian in age. Garnets and sillimanite are characteristically developed; pegmatites and quartzose masses also form irregular segregations or lenses along planes of schistosity. Replacement of schists by pegmatites is a common feature. (2) The general strike of the schists is remarkably uniform, being approximately in a northeast and southwest direction. (3) The outcrop of the Broken Hill lode has the same strike as the country rocks. (4) Three belts of schists occur in immediate association with the lode, namely: (a) A belt of dense gneissic rocks and amphibolites forming its eastern wall; (b) a similar belt forming the western wall; (c) a soft, weak, and well laminated series of mica schists and allied rocks, some 660 ft. in width, alongside of and through which the Broken Hill ores occur. (5) At the surface, and in the open-cuts, the lode appears to partake of the nature of a fissure developed along a plane of schistosity. At certain places along the lode outcrop the weak schist mass of the hanging wall is highly contorted; nevertheless, no sympathetic foldings of the schists forming the associated dense country are observable. The weak schist-mass never leaves the fissure, but preserves the same general strike as the latter, with marked local deviations from this direction. In general aspect it is analogous to a roof of corrugated iron which has the same general strike and dip as that of the frame to which it is attached, and yet has numerous puckerings or corrugations, causing marked local deviations from the general strike. (6) The ore masses apparently developed are to the west of the fissure. An exception to this appears to occur in the Proprietary mine. (7) The ore masses are, notably, replacements: (a) along the fissure itself; (b) along weak layers in the schist corrugations. Such shoots of ore have steep southwesterly pitches to the south of Block 14, and a steep northeasterly pitch to the north of the same property. (8) At first sight the shoots are strikingly suggestive of saddle-reef formations. They, apparently, curve sympathetically with the corrugated foliation planes. (9) The so-called saddles, however, are intimately related to the fissure or foot-wall; they are generally continuous with it on one side—appearing to spring out of it—and though their longer axes are not strictly in the same plane as that of the foot-wall or fissure, they are so intimately related to it as to suggest their absolute dependence on it for their existence. (10) The saddles do not occur in the strong schist belts, and are not found outside of the weak crumpled zone. Underneath the shoots or saddles the foliation planes exist in anticlinal form, ore and country having a familiar general curvature.

They do not, however, represent filling of fissures formed between folded planes, but represent rather the replacement of huge masses of weak schist structures; for throughout the huge stopes abundant traces of the numerous foliation planes may be seen entirely traversing the ore masses. Horseshoes of 'mullock' occur, completely surrounded by ore, yet so disposed as undoubtedly to represent remnants of crumpled schists in place, and not fragments filling fissures. On the upper portions of the 'saddles' the ore commonly grades into the country. (11) The fissure is not characteristic of the zone of fracture. It is rather insignificant in itself, and is important only by reason of the intense activity of the solutions which rose along it. The ore-associates also point to a deep-seated origin for the lode. Thus garnets, rhodonite, secondary mica, and quartz are abundantly represented. Fluorspar also occurs.

The deductions from the foregoing are as follows: a series of rocks occupying the Broken Hill area had been changed to crystalline schists. Garnetiferous schists, pegmatites, and amphibolite had been developed while basic cross-dikes had been altered into schists. One belt of weak, well laminated mica schists and allied rocks had been developed between two resistant series. Either the intensely laminated appearance of this weaker belt was due to original structural weaknesses or, as seems more probable, to the shearing of two dense rock series upon each other. Later, a narrow but strong fissure was formed along this line of weakness (plane of schistosity). A rotatory movement apparently now acted powerfully on the weak schist buffer. Strong parallel corrugations were developed in it. These were arranged vertically under each other north and south of Block 14, and their main axes lay mainly in planes approximately parallel to, and alongside of, that of the fissure. Individual corrugations represent so many flexings of the same schist belt. Heated waters—or water and water vapors—rose along the fissure and replaced the weaker schist foliae of the associated corrugations. In the presence of great pressure and strong reagents (hydrochloric, hydrobromic, hydrofluoric, and other acids), they simultaneously attacked the weaker walls of the main fissure and the intensely laminated foliae of the corrugations. The stronger layers offered greater resistance to percolation of the waters and thus a saddle-like set of ore-masses was developed. Firstly an intense silication occurred with later great development of amazonite, rhodonite, garnet, also zinc, lead, and silver sulphides. In many cases an imperfect replacement occurred, permitting the tracing of the various stages in replacement.

The geologic permanence of this field is thus suggested. The economic side of the question cannot be satisfactorily discussed until the corrugations (and the fissure) so far exposed by actual mining operations have been carefully examined, so as to apprehend the scheme of crumpling—if any such exist—and the class of schist or schist-structure most amenable to replacement. A knowledge of the varying quality and character of the orebodies with depths so far obtained is also necessary.

*Paper in *Economic Geology*, Vol. III, No. 7, 1908.

METAL DISTRIBUTION IN THE VEINS OF SCANDINAVIA.

By HJALMAR SJÖGREN.

*As several of the Scandinavian mines have been worked for centuries, our knowledge of the distribution of the metals in the different parts of the deposits is based on long experience. To begin with, I will give a few instances of the decrease of the copper percentage with depth in some of the principal copper mines in the Scandinavian peninsula. These occurrences we must consider as primary features. The rock-surface of the Scandinavian peninsula was, during glacial time, so deeply eroded that all products of surface weathering which had gone on during the greater part of Mesozoic and Cainozoic time were removed by the ice. The ore deposits of the Scandinavian peninsula are thus in general to be considered as the roots or the deeper parts of the original deposits, now laid open for observation, and in this respect they claim special interest.

The famous Falun mine has a history which can be followed for 750 years. Until the end of the nineteenth century it yielded more copper than any other separate mine in the world, having produced, in round numbers, 500,000 tons of copper, 15 tons of silver, and 1 ton of gold, representing a sum of about 1000 million Swedish crowns or about \$27,000,000. The pyrite occurs enclosed in a quartzitic rock derived from the surrounding granitic gneiss, which is Archean. This metamorphism, which probably took place in connection with the formation of the ore, consisted in the solution of the greater part of the basic constituents of the granite, so that the remaining rock consists almost exclusively of silica. The ore-bearing rock is traversed by eruptive dikes, acid as well as basic, of felsitic and dioritic nature. A connection between them and the formation of the ore has not, however, been ascertained. The largest orebodies at Falun are stocks of pyrite of conical form, with points downward. The largest of these stocks ceases at the rather moderate depth of 332 m.; no continuation of it has been found. The pyritic orebodies are enclosed in peculiar rock-masses consisting chiefly of talc and chlorite (skölar) and carrying several minerals of secondary origin. The 'skölar' enclose the conical orebodies and separate them from the surrounding quartzite; they thus get a shape which may be compared with cornets, filled with the pyritic masses.

The distribution of the rich copper ore was chiefly close to the inner side of the skölar and in the skölar themselves. Their central parts contained much less copper. There is also a general decrease of copper with depth.

In recent years an ore containing about 3% Cu has been mined, and the ore percentage has been 33%, that is, the average amount of Cu obtained from the rock mined has been 1%. In the older parts of the mine, according to tradition, a far richer ore was obtained, probably yielding 10% Cu or

more; otherwise an annual production of more than 3000 tons of copper would have been impossible.

A similar case is presented by the mines at Atvidaberg, which also had their palmy days in past centuries and were abandoned about thirty years ago. The Bersbo mine, where the deposits are now being explored at a depth of 410 m., and the Mormors mine, which, when abandoned, had reached a vertical depth of 407 m., are now the deepest mines in Sweden. The ores, which in the Bersbo mine occur at the contact with a diorite body, consist of copper pyrite, pyrrhotite, and sphalerite in a quartzose gangue. In this mine the decrease with depth both of the dimensions of the veins and of the copper percentage of the ore is observed. A striking feature in the Bersbo mine is the downward increase of the zinc-blende with proportional decrease of copper.

The above two examples are taken from among deposits of the Archean system. Instances of the same kind regarding the decrease of the copper percentage with depth are afforded by the numerous pyrite deposits associated with gabbro and occurring within the metamorphosed Silurian schists that constitute a great part of the high mountains of the Scandinavian peninsula. Such an instance is Vignäs, on the western coast of Norway, a fairly large deposit, that yielded, from 1865 to 1894, 900,000 tons of pyrite and copper ore. The deposit consists of a system of veins in gabbro, which rock in the parts adjoining the veins is altered into a schistose chloritic rock. In the upper parts of the deposit the average copper content was 2 to 2.25%. This percentage, however, decreased quite regularly with depth, being at the greatest depth attained, namely, 735 m., reduced to less than 1 per cent.

Vignäs is a deposit with a high dip—at least 70°. The numerous deposits of the same type that have a flat position present different features from those of Vignäs with respect to the copper percentage. In them no decrease of the copper is observable, when followed in the direction of the dip even to a considerable length.

The mines of Røros and Sulitjelma offer instances of this. In the former of these mining districts, where one can look back on a period of 250 years of mining, the pyrite bodies have been followed, in the Storvarts mine, 1350 m. with a dip of 8 to 10°. In the Mug mine, also with an average dip of 8 to 10°, the orebody has been followed 1080 m.; in the King's mine (Kongens Grube), in which the ore lies partly horizontal, and where in places it has a very slight inclination, the deposit has been followed no less than 2000 m. in the direction of the dip, without any observable change as to the copper percentage of the pyrite. At Sulitjelma the case has been found to be the same, though the orebodies there have a somewhat greater dip than at Røros, not amounting, however, anywhere to 30 degrees.

It thus appears that there is a decided difference between deposits with a low degree of inclination (30° or less) and such as have a steeper dip, the copper percentage of the former continuing the same with depth, while in the latter it decreases rather rapidly as the deposit is followed downward. This

*Abstract of paper in *Economic Geology*, Vol. III, No. 7, 1908.

rule is valid with regard to the deposits in Archean rocks (Falun and Atvidaberg) as well as to those of Silurian (Vigsnäs, Rösos, Sulitjelma), and therefore seems to be universal.

This fact can, according to my view, be accounted for only by assuming the copper in the said deposits to be a function of the vertical depth, and the formation and precipitation of the copper substances from the magmatic solutions to have been dependent on the hydrostatic pressure that existed at different levels below the surface as it was when the ores were formed.

The above circumstances are evidently not only of great theoretical interest, but of equally great practical importance. For it is obvious that in the valuation of a pyrite deposit of this type one must attach far greater importance to the inclination of the deposit than has hitherto been usual. It follows from the above that a pyritic deposit of this type, other things being equal, must be considered of higher value, if it has a flat or slightly inclined position, than if it stands more vertically.

Also with regard to the lead and silver mines, experience warrants the same conclusion. The oldest and most important silver mine in Sweden is the Sala mine, which has been worked for more than four centuries on a metasomatic deposit in dolomitic limestone. The mineralization obviously started from a system of fissures (skölar) which with depth join in a trunk fissure (the Great Sköl), which traverses the deposit longitudinally. The percentage of lead has, on the whole, notably decreased downward, so that no more sinking has been carried on during the last 20 years, the greatest depth being now 320 m. Mining is going on exclusively on the higher levels in such portions of the ore as were formerly regarded as too poor to hoist, but which, however, are richer than the lower portions of the deposit in general. With increasing depth a general 'dilution' of the deposit through dolomitic limestone is observable. The silver value has decreased still more rapidly than the lead percentage; the rich silver minerals which, together with argentiferous galena occurring on the higher levels, namely, silver amalgam, argentite, and native silver, not being found at greater depths.

Another deposit of similar nature, though of smaller extent, is the lead-silver mine of Kallmora, Wästmanland, which has been worked on an argentiferous galena lying in limestone. Even at a depth of about 200 m. this deposit was found to be so strongly 'diluted' with lime that the working had to be abandoned.

An interesting instance of decreasing percentage of metal with depth is afforded by the silver mines of Svenningdalen, in Norway. They were worked on a system of parallel veins traversing at right angles a series of schists and limestone beds of Silurian age, as well as an intrusive granite. The argentiferous minerals in Svenningdalen are, besides a galena, containing about 1.5% Ag, fahl-ores rich in silver and proustite.

As the system of veins in Svenningdalen has been followed only to a depth of 100 m., it might be sup-

posed that the decrease of the metal percentage at that depth is but accidental, but the fact that the same relations occur in the two mines, the Svenningdals and the Jakob Knudsens, indicates that it is not accidental. The mines of Svenningdalen also offer instances of the enriching influence of vein-crossings; a rich bonanza was found in the crossing between the main vein of the Svenningdal mine and the so-called southwest vein. Also in the Jakob Knudsen mine it has been observed that the metal content is richest at the vein-crossings.

From the copper and lead-silver ores here mentioned the Swedish iron ores differ with regard to the constancy of metal percentage; in these ores no general decrease of the iron with depth has been shown. These ores, so far as they belong to the Archean formation, are referred to two classes. One class comprises ores associated with basic eruptives of the gabbro group; they are products of magmatic differentiations which have taken place in the rock magma itself. Owing to their high percentage of titanium and their often low percentage of iron, they offer great difficulties to the metallurgist, and though there are vast supplies of these ores, they

Graphic Representation of Decrease in Silver-Content With Increased Depth.

are as yet of no commercial value. For the ores of the other class, which occur associated with metamorphosed quartz-feldspar rocks of eruptive character, such as granulite, hälleflinta, syenite porphyries, and others, I have proposed the name dia-magmatic. They are evidently genetically connected with the aforesaid quartz-feldspar rocks, but have been produced through a differentiation process in a deeper zone, by which the iron-magnesia-lime-bearing material has been segregated from the silica-alumina-alkali material, and, being kept in solution through water and other mineralizers, has at the later stage formed epigenetic deposits. This is the same type to which C. K. Leith has recently proposed the name 'pegmatite type.' Ores of these classes have, it is true, undergone changes in the surface zone affecting the degree of oxidation of the iron; moreover, the minerals of the pyroxene and garnet groups have given rise to amphiboles, and to epidote, chlorite, and talc minerals, but on the whole the ores show no changes in richness of metallic value toward the depth. If, as is frequently the case, individual ore-bodies cease even at slight depths, they are in such cases followed by others of the same character.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING-MACHINE.—No. 906,221. William G. Halbert, Danville, Illinois.

In a mining machine, the combination, with a carriage, and a cutter chain adapted to travel about the same, of a sprocket wheel mounted on said carriage in engagement with said cutter chain and having a hollow hub journaled in said carriage, and a supplemental cutter having a shank of substantially the same length as said hollow hub, slidably mounted in said hollow hub and held against rotation therein.

MINE-TIMBER.—No. 907,554. Zacariah Z. Ansbach, Silver Creek, Pennsylvania.

In combination with a pair of opposite side timbers inclined toward one another so as to have the least space therebetween at their upper ends, with inverted V-shaped projections on said upper ends, a pair of roof timbers formed with V-shaped notches on their outer ends and their under sides adjacent said outer ends to receive said projections of the side timbers, said roof timbers having their meeting ends beveled and abutting one another.

DRILL-HOLE CLEANING ATTACHMENT FOR HAMMER-DRILLS.—No. 907,430. Daniel S. Waugh, Denver, Colorado.

A drill body provided with a hollow drill bit, a conduit connected with the forward end of the drill body for delivering the drill-hole cleaning fluid to said hollow drill bit, a valve body interposed between the forward and rear members of the said conduit and threaded in the body of the drill, the valve piece passage therein located in said valve body, a connection between the motive fluid receiving portion of the drill body and the chamber of the valve whereby motive fluid is supplied from the drill body to the valve, the valve being capable of adjustment to allow the motive fluid to pass through the forward member of the conduit while communication with the rear member is cut off, or to open communication between the two members of the conduit

while the motive fluid is cut off, and suitable means for delivering motive fluid to the drill-hole independently of the operation of the drill, substantially as described.

METHOD OF MINING.—No. 906,765. William G. Anderson, Smuggler, Colorado.

The method of mining which comprehends running levels along the orebody, connecting these levels by a suitable passage way, working out the ore on each side of the passage way by a system of benches, putting stullage and lagging into the worked out stopes, and filling the waste material into the vacant stope on top of this lagging, carrying down manways with the stope and collecting the broken ore at the bottom of the passage way in a chute.

APPARATUS FOR HANDLING MATTE AND SLAG OF COPPER BLAST-FURNACES.—No. 906,622. George K. Fischer, New Rochelle, New York.

A system of the kind set forth, having a means for separating slag and matte, a working floor contiguous thereto, a tunnel arranged beneath said floor and adapted to receive a plurality of slag receptacles side by side, said receptacles mounted to be moved through said tunnel and said floor having an opening to the tunnel, and means for delivering slag from the separator through the opening and to either of the receptacles.

ORE-SEPARATOR.—No. 906,535. John G. Kirksey, Carthage, Missouri.

The combination with an inclined table having a flat uninterrupted upper surface; of a plurality of similar riffles secured upon and disposed entirely above the upper surface of the table, said riffles being inclined upwardly toward the discharge end of the table and each riffle comprising a flat elongated strip gradually increasing in thickness toward one end, the side edges of the strip being straight from end to end and perpendicular to the faces thereof, the upper and lower faces of the riffle being duplicates, said riffles forming grooves therebetween, the top of the table constituting the bottom of the grooves.

COMPANY REPORTS.

PHELPS, DODGE & CO.

This corporation controls the Copper Queen Consolidated Mining Co., the Moctezuma Copper Co., the Detroit Copper Mining Co., of Arizona, and the Stag Canon Fuel Co. In order to get these stocks listed on the New York and Boston Stock Exchanges, it was found advisable to form a corporation (with a capital of \$50,000,000) by which the properties of the foregoing four companies might be held under one name. The majority of the stock of each of the companies is held by Arthur C. James, Cleveland, H. Dodge, James McLean, James Douglas, and their families.

In the consolidation the Copper Queen is valued at \$27,000,000. It is paying \$17 per share on 200,000 shares. In 1907 this mine produced 63,341,055 lb. copper and earned \$4,471,137. The property covers 135 mining claims at Bisbee, Arizona, and a large portion of the ground is as yet undeveloped. The smelter, at Douglas, has a capacity of 3000 tons per day. The company does custom smelting and conducts a general mercantile business, with stores at Bisbee, Douglas, and Naco.

The Moctezuma property consists of 2500 acres of mineral ground in Sonora, Mexico. The chief mine is called the Pilares. An orebody 1700 by 1200 ft. has been proved down to 700 ft. A narrow-gauge railroad, 5 miles long, connects the mine with the concentrating mill at Nacozari. This mill has a capacity of 2000 tons per day. In 1907 the production of copper was 9,640,390 lb. and the net earnings \$833,236. A production of 2,000,000 lb. copper per month can now be maintained.

The Detroit mines are in the Clifton district, Arizona, where the company owns 145 mining claims, yielding 36,000 tons per month of 3% copper ore. This is concentrated to 15% and smelted at the Morenci smelter, also owned by the company. In 1907 the production was 17,974,581 lb. copper and the earnings \$814,874.

BUNKER HILL & SULLIVAN.

The full name is the Bunker Hill and Sullivan Mining and Concentrating Company. The Bunker Hill mine was originally consolidated with the Sullivan, and other claims have been added until the company owns 3000 acres. The mines are above the town of Wardner, in the Couer d'Alene region, Idaho. The office and mill are at Kellogg, two miles below Wardner. The latest report is for the fiscal year ending May 31, 1908. During this period the mine produced 330,730 tons of concentrating ore, at a cost of \$511,288, so that the cost of mining was \$1.548. The mine also produced 4340 tons of crude ore, which was shipped to the smelters, and the cost of mining this ore was \$1.954 per ton. At the mill 330,930 tons were concentrated at a cost of 37.2 cents per ton and 72,468 tons of concentrate and middling were shipped, besides 4304 tons of crude ore, making the total shipments 76,773 tons. Thus the total expenses were \$731,020, or \$2.18 per ton of crude ore. The total receipts from shipments of concentrate and crude ore were \$3,391,426, from which are deducted the freight and treatment charges, aggregating \$1,351,654, leaving \$2,039,771, from which the operating costs of \$731,020 are subtracted, leaving an operating profit of \$1,308,751. The average value obtained for lead was 3.995c. per pound, and for silver, 60.07c. per ounce. Dividends to the amount of \$1,380,000 were paid.

CONIAGAS.

This silver mine is at Cobalt, Ontario. The name originates from compounding the chemical symbols of the metallic elements cobalt, nickel, silver, and arsenic, all of which exist in the ore. The total silver produced in the year ending October 31, 1908, was 1,444,229 oz. at an average price of 52.3c., as compared to 67.05c. last year. The ore reserves are estimated to contain 13,000,000 oz. silver. The yield comes from picked ore, which is sold to smelters, and concentrating ore, of which 14,064 tons yielded 297 tons of concentrate. The total receipts for the year were \$727,195,

on which the operating profit was \$501,718. The dividends absorbed \$440,000.

ASHANTI GOLDFIELDS, WEST AFRICA.

The tonnage treated at this mine for the year ending June 30, 1908, was 59,150, from which, together with that from other trifling sources, 40,825 oz. gold, and 3985 oz. silver was extracted. The profit realized was £80,942. After the usual provision for depreciation and development, and writing off £15,000 from shares in the Sansu mine, a net profit of £34,646 was obtained. The directors decided to write off out of profit and loss account the balance of expenditure on the main shafts and development, amounting to £57,008, leaving a credit balance of £4752. The development work has revealed ore-reserves available for stoping of 135,000 tons, leaving an average gold tenor of 14.6 dwt. Indicated ore increases this by 80,000 tons in the Justice mine, estimated to carry 12 dwt. gold. Thus the mine is more than 2 years ahead of the existing milling capacity. The old stamp-mill and cyanide plant has been found unsuited to the ore from the new Justice mine, and a system of sliming and filter-pressing will be resorted to, the plant for this purpose to have a capacity of 2000 tons per month. The equipment will be in operation in January of this year. This plant will be duplicated during the year; a four-unit roasting plant will be added, a central electric station will be installed, and a more comprehensive scheme of power centralization will be placed in service as a means of economizing fuel.

PIONEER MINING.

According to the annual report of Jafet Lindeberg, the president and general manager of the Pioneer Mining Co., of Seattle, the gross output of gold for the year ending on October 10, 1908, was \$974,310. The net profits were \$571,903. Out of the profits the company spent \$120,000 in purchase of new property. A dividend of 3%, absorbing \$150,000, was paid on November 16. Prospects for the next season are excellent and the output, barring labor troubles, is expected to reach \$800,000 easily. The company owns a large area of placer ground near Nome, Alaska, and handsome profits for several years are anticipated.

KALGURLI GOLD MINES, WESTERN AUSTRALIA.

This mine produced 127,008 tons of ore during the year ending July 31, 1908, from which a recovery was made averaging £2 16s. 0.48d. per ton. The tailing averaged 3s. 7.83d. per ton. The costs for mining were 8s. 5.11d. and for treatment 12s. 3.39d. per ton. Dividends amounting to £180,000 were paid, bringing the total profit-division to date, since 1901-2, to £720,000, which is equivalent to £6 per share. This has been realized from a total of 585,375 tons of ore. The ore during the year was derived from all parts of the mine, from the surface down to the 1350-ft. level, the heaviest production coming from the zone between 750 and 1000 ft. Development likewise has been continued throughout the mine, discoveries of importance being made within 255 ft. of the main shaft on the surface. The manager, R. S. Black, reports estimated ore reserves of 510,000 tons above the 1350-ft. level. The orebodies are erratic, and the grade extremely so, causing definite measurement and valuation to be difficult, without performing an amount of development work that would entail expenses out of proportion to the tonnage made ready for stoping. The manager says: "Under the system of working, an average of 55s. (per ton) has been maintained. Had I found that this grade necessitated the undue depletion of the richer ore I would have lowered it, as I shall at any time do if there is necessity for it." Ore was not developed at any deeper level than during the previous year, so that the addition to the ore reserves has not kept pace with the extraction, and the available tonnage shows considerable diminution. As will be seen, however, the management has prudently kept development so far ahead of mill-requirements that there is a 4-year supply on hand, giving ample time for extensive exploration of the deposit. Details of mining and milling costs are not given in the report.

A Successful Tramway.

By DON MAGUIRE.

Among difficult feats of tramway building in Utah may be mentioned the aerial wire-rope tramway completed during the early part of August 1908 by the Broderick & Bascom Rope Co., of St. Louis, for the Napoleon & Maghera Copper Mining & Reduction Co., of Ogden, Utah.

The property is situated on the Sierra Madre mountain, in Box Elder county, Utah. This is one of the steepest and highest portions of the Wasatch range. The district produces gold, silver, copper, and lead ores; the lodes occupy fissures in the granite. The most productive mines are the Eldorado, Napoleon & Maghera, Santa Maria, and the Prince of India. The Napoleon & Maghera property, on which the tramway has been built, covers five large lodes, four of which yield copper ore containing gold and silver. The copper veins are situated in the western part of the property

The Napoleon & Maghera Tram.

in a locality difficult of access, so that during three years all supplies were furnished to the several mine openings by means of a burro train that traveled over an almost inaccessible trail.

The distance from the mill-site, at the base of the mountain, to the mouth of the principal adit is approximately 2632 ft. The contour over this distance is rough beyond description, and many mining experts were of the opinion that it was not practical to install an aerial tramway, but Broderick & Bascom undertook the contract and have installed a plant that is a success in every respect. The tramway engineer began work in September 1907. An immense volume of rock had to be blasted from the sides of the steep granite cliffs in order to secure a footing for the towers; at other places, foundations of masonry were necessary for the same purpose; near the upper terminal, or loading station, a gap had to be mined and blasted out of the sharp ridge that separated the mouth of the adit from the crooked canyon, down which the ore is transported to the mill over the tramway. From August until December the work was pushed vigorously; inclement weather and heavy snow-storms intervening, work on the tramway was discontinued, but a small force of men took a contract to deliver a large lot of heavy timbers required for the terminals, ore-bins, and other purposes; these timbers were passed

over the cliffs by means of block and tackle, cables, and horse-power. After three months of laborious work the last of the timbers and machinery were transported to their proper place and early in June 1908 Broderick & Bascom's engineer returned to complete the work that was discontinued in December 1907. With a force of 12 men the engineer continued the construction, and on the evening of August 14 the tramway was completed and operated successfully. The present capacity of the tramway is 300 tons every 10 hours. This can be doubled by increasing the number of buckets. In no part of the Rocky Mountain country is there a tramway that works more smoothly.

Commercial Paragraphs.

THE COAHUILA MINING & SMELTING Co., Ltd., of Viesca, Coahuila, Mexico, will be interested in receiving descriptive literature on pneumatic ore-separating machinery.

The testing plant of the ELSPASS ENGINEERING Co. and L. S. PIERCE has been moved to the rear of 1625 Champa St., Denver, Colo. The offices of the above firms are at 1650 Champa street.

THE CHICAGO HOUSE WRECKING Co. has sent us copies of testimonial letters attesting the satisfaction they have given customers in widely scattered districts of the United States with large shipments of lumber, building material, and other merchandise.

THE ECONOMIC MACHINERY Co., Denver, Colo., manufacturer of the Deitz Airoelectric rock-drill and the Fairchild automatic vacuum-filter, is building eight of the Deitz Airoelectric rock-drills for the Crystal River Marble Co., of Gunnison county, Colorado.

WM. AINSWORTH & SONS state that they have received an order for three 18-in. precision wye levels and two 5-in. precision transits from the Aqueduct Commission in charge of the construction of the Los Angeles Aqueduct, awarded chiefly on account of the interchangeability of parts, rigidity, and workmanship.

THE TRIPLEX ROLL Co., Denver, has been incorporated for \$350,000, with J. H. Elspass, Henry Eggers, and Mary L. Jacobs as incorporators. It is the owner of the patents of the Triplex rolls, which have been in use in different mills throughout the country for the past two or three years. Their catalogue is now ready for distribution.

THE FOOS GAS ENGINE Co., of Springfield, Ohio, is furnishing a producer-gas plant to the Standard Optical Co., at Geneva, N. Y. The engine will be a 100-hp. three-cylinder Foos vertical, from which power will be transmitted by rope drive. The producer will use Pennsylvania anthracite, and is so arranged that a portion of the gas will be drawn off and used for annealing furnaces. The plant will contribute materially to the economical operation of the factory.

Catalogues Received.

THE THOS. H. DALLETT Co., Philadelphia, is distributing its catalogue No. 100, describing air-compressors.

THE JEFFREY MFG. Co., Columbus, Ohio, has just issued a catalogue, No. 67D, on its line of Century rubber belt conveyors.

THE TAYLOR IRON & STEEL Co., High Bridge, N. J., is distributing a handsome pamphlet on 'Tisco Manganese Steel for Crusher Plants'.

JOHN V. N. DORR, Denver, has published an attractive booklet describing and discussing the advantages of the Dorr classifier and Dorr continuous slime thickener.

THE ROBINS NEW CONVEYOR Co., Chicago, will send, upon request, a copy of its Bulletin No. 1, which is a re-print of a paper read by C. Kemble Baldwin, on 'The Belt Conveyor' before the American Society of Mechanical Engineers.

THE AMERICAN BLOWER Co., Detroit, Mich., has recently issued new publications as follows: Catalogue 244, on variable speed engines; Catalogue 247, on steam traps; Circular 242, on electric forge blowers; and Circular 246, on shop heating.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING PARTNERSHIP.

Two persons, under a lease of mining property, agreed to work the property jointly, each to bear one half the expense. Where one put in his own work and the other furnished a third person to do his share of the work, they were engaged in a joint enterprise for the purpose of carrying out the provision of the lease and were equal partners. A mining partnership exists where the several owners of a mine co-operate in working it.

Walker v. Bruse, (Colo.) 97 Pac. 250, July, '08.

LIEN ON MINING PARTNERSHIP PROPERTY.

Partners operating oil leases have a lien on the firm property for advances made by them in payment of the firm debts; but no such lien exists as against the product of oil wells which have been divided. The lien remains valid as against any property used by the firm in operating the leasehold.

Greenlee v. Steel Smith, (W. Va.) 62 Southeast. 459, Sept., '08.

STATUTES REGULATING MINES—CONSTRUCTION.

Statutes requiring coal corporations to always keep on hand near the mine, stretchers, bandages, medicines, etc., for use in case of injury to the workmen, are in derogation of the common law, highly penal in character, and should be strictly construed.

Sourwine v. McRoy Clay Works, (Ind. App.) 85 Northeast. 782, Oct., '08.

CONDEMNATION OF RIGHT OF WAY.

A case of peculiar interest to mining companies has recently been decided by the Supreme Court of Tennessee. It appears that the Alford Phosphate Co. owns 300 acres of phosphate lands, estimated to contain 500,000 tons of phosphate rock. It also appears that the Duck River Phosphate Co. owns large phosphate mines in the same vicinity, and that the latter company owned and operated a private railroad from its mines, a distance of nearly 5 miles, connecting with the Nashville, Chattanooga & St. Louis railway. This private road for a distance of about 2 miles is built along the banks of Duck river and at the base of a bluff or cliff 30 or 40 ft. high. Owing to the peculiar contour of the country, there was no other practical place for another railroad, from the mines of the Alford Phosphate Co.; this company, desiring an outlet for its products, attempted to condemn the right of way and the tracks of the Duck River Phosphate Co. for a distance of 2 miles where it ran along the river bank and under such bluff, to use in connection with a private railroad used and operated by the Alford Phosphate Co. It was decided by the Court that the right cannot be conferred upon either a public or private corporation to condemn property for private use; and that if the condemnation was for a public use, the right of way and tracks of an existing private railroad could not be condemned without condemning the entire road. And the Court held invalid an act of the Legislature which gave a phosphate company the right to condemn property for a railroad, and that a provision of such act declaring property condemned by such a corporation a public road could not change the character of its use; and that the act was invalid as authorizing the condemnation of property for private purposes.

Note.—This decision of the Tennessee court in no way conflicts with or destroys the right of one public railroad in mountainous districts, under a United States statute, as well as under statutes of some States, from condemning, longitudinally, the tracks and right of way of another railroad through gorges or chasms or on mountain sides, where there is only room for one track.

Alford Phosphate Co. v. Duck River Phosphate Co., Tenn. 113 Southwest. 419, July, '08.

Publications Received.

Any of the books noticed in these columns are for sale by or can be procured from the MINING AND SCIENTIFIC PRESS.

SMITHSONIAN INSTITUTION: ANNUAL REPORT OF THE BOARD OF REGENTS FOR 1907. *Washington. Government Printing Office. 1908.

The annual report of the Smithsonian Institution contains satisfaction for a wide range of scientific appetites. Most of the contributions have an economic leaning, as for example the notable paper on the 'Steam Turbine' by Charles A. Parsons; on 'Mechanical Composition in Printing' by A. Turpain; the timely discussion on 'Electric Trunk-Line Operation' by Frank J. Sprague; and another on 'Electric Wave Telegraphy' by J. A. Fleming. The 'Properties and Natures of Electric Radiations', having power to ionize gases, to effect photographic plates, and to excite phosphorescence, are discussed by W. H. Bragg. A review of the present status of 'Electro-Metallurgy' is given by John B. C. Kershaw, and Thomas W. Smillie contributes an account of the 'Recent Progress in Color Photography'. As a matter of antiquarian interest, Adrien de Mortillet, president of the Société Préhistorique de France, shows that the manufacture of bronze was known to the pre-Colombian inhabitants of the Andean plateau.

To geologists, and students of ore deposits, the paper of leading interest will be the 'Geology of the Inner Earth' by J. W. Gregory. The argument favoring the planetismal, advanced by Chamberlin, theory is weightily summed, and the lack of demonstration of the existence of a barysphere is made plain. A comparison of the density of the earth with that of meteorites calls attention to a resemblance that is striking. Strutt's estimate of a uniform temperature of 1500° C. for the interior of the earth within a 45-mile exterior envelope, is brought into prominence, as conforming to other conceptions of the state of the earth necessitated by recent investigations. The segregation of ores by osmotic pressure from basic magmas is on the whole controverted. Other notable papers are on the 'Salton Sea', 'Inland Waterways', and the 'Present Position of Paleozoic Botany'.

WATER POWER ENGINEERING The Theory, Investigation, and Development of Water Powers. By Daniel W. Mead. 8vo.; 787 pp.; index; ill. McGraw Publishing Co., New York. 1908. Price \$6.

As a practical handbook this volume is to be recommended. Mr. Mead possesses the true educator's faculty of simplifying his subject; he develops the mathematical side without involving it in obscurity. In fact, assumption of familiarity with the fundamentals is not made; the author starts in every case with first principles, leading with clear exposition to the abstruse problems. In this regard the work is unusual. It is in the highest sense a guide to the correct statement and solution of the problems arising in the development of water power. After introductory chapters on power and hydraulics, catchment areas, rainfall, disposal of rainfall, run-off, measurement of streams, follow discussion of water-wheels, hydraulics of the turbine, selecting and testing turbines, the load-curve and load-factors, speed-regulation, governors, design of plant, examples of water-power plants, and so on, including cost, value, and sale of power. A valuable feature consists in the elaborate bibliography which is appended to each chapter.

A STUDY OF ORE DEPOSITS FOR THE PRACTICAL MINER. By J. P. Wallace. 8vo., 340 pp., Ill., Index. Hill Publishing Co., New York. Price \$3.

The ECK DYNAMO & MOTOR Co., Belleville, N. J., is issuing a series of bulletins describing its product. A useful feature of these bulletins is one or two pages on which is given data to aid in the selection and installation of the apparatus. Another notable feature is the fact that the dimensions of the different types are given in great detail.

EDITORIAL.

LOS ANGELES will soon receive deserved recognition as a mining base by the establishment of a United States assay office. The bill which has passed the Senate carries an appropriation of \$20,000 for annual expenses of maintenance.

THE AMERICAN Institute of Mining Engineers will meet at New Haven on February 23. A number of interesting papers are announced, including one on 'A Sea-Level Canal at Panama', a communication to which much publicity has already been accorded. It should provoke an interesting discussion.

THE CANADIAN Mining Institute meets in eleventh annual session at Montreal on March 3, 4, and 5. The proceedings promise to be interesting, many papers being on the program, including addresses from Messrs. James F. Kemp, Heinrich Ries, F. Cirkel, S. S. Fowler, H. E. T. Haultain, A. C. Lane, J. C. Murray, and George R. Smith.

SO MUCH good work has been done in Alaska by the Geological Survey that we venture to make a suggestion: Every summer prospectors wander across the wilderness of the interior, and up the many shallow rivers, in search of gold. These men test the creeks and obtain information as to the character of the gravel, the depth to bedrock, and other facts of practical value, all of which are lost. Parties of men will penetrate laboriously into a supposedly new district only to find evidence of previous prospecting. Would it not be possible to collect information from these nomadic diggers, for instance, at a junction point, like Fort Gibbon, where so many trails meet? An intelligent young man stationed there during the summer could, we believe, place on record a large amount of information gathered from wayfarers and likely to be useful to other prospectors.

DISCRIMINATIONS by the railroads assume varying forms under the restrictions imposed by Government prosecution. The favorites continue to be favored, which necessarily means participation by individual railroad officials in the benefits conferred nominally upon outsiders. The prevailing ruse is to farm out a portion of the common carriers' duties to shippers, among whom the evils flowing from private ownership of freight cars are more difficult to overcome. The allowances made from haulage charges in consideration of the shipper supplying rolling stock prevent competition by less fortunate rivals. In private elevators, lighters, and the like, are also found convenient means for disguising rebates that embarrass shippers who will not share

their profits with the railroads. Manifestly the transportation companies must be compelled to perform similar duties at uniform rates for all.

TENDENCIES to check monopoly by resort to the leasehold system instead of surrendering national resources in fee simple to individuals are steadily growing. The latest example is the proposal to lease phosphate lands. By executive order phosphate deposits on public lands were recently withdrawn from location. The passage of the bill now introduced into Congress would permit the utilization of phosphate deposits, thus creating a larger demand for sulphuric acid, the ultimate result benefiting both smelter and farmer. A feature of the bill prohibiting the exportation of phosphate is most commendable.

LEGISLATION to protect mining investors is becoming popular. The legislature of the State of Washington is being urged to pass new laws and the Governor in his biennial message makes the following recommendations:

"Incorporations based upon unpatented claims should be declared illegal, since such holdings may lapse at any time; or else the board of directors of such corporations should be made personally liable for all debts contracted until the claims are patented at the expense of the promoters; no transfer of promoters' stock should be permitted until all of the treasury stock has been disposed of; all moneys derived from the sale of treasury stock should be placed in escrow until at least one-half of the treasury stock has been sold for cash, and unless such an amount is sold within a certain time—say six months—all such moneys should be returned intact to the subscribers, and such other provisions should be incorporated as will adequately safeguard the interests of investors."

Some of these provisions are excellent. Any enactments that will stop bad practices without injuring legitimate business should receive the support of earnest citizens.

FROM the latest circular issued from the office of the Secretary of the American Institute of Mining Engineers, we note with interest the nominations for officers this year: for president, Mr. David W. Brunton is named, and no man is better fitted to be titular head of the profession of mining engineering in America; for vice-presidents, Messrs. H. V. Winchell, W. L. Saunders, and W. C. Ralston are nominated. Two of these three are obviously excellent selections, but against the third we deem it proper to protest. Before performing an ungracious duty we beg to state that no criticism is implied upon our fellow townsman, Mr. W. C. Ralston, who probably was not consulted as to his nomination, and if we find ourselves in the difficult position of criticizing the management of the Institute, it is a task not performed with any eagerness, for we yield to none in our respect for Dr. Raymond and in appreciation of his services to the Institute in particular, and to the American mining industry in general.

After all, the American Institute of Mining Engineers has a name as a national organization of professional men, even though a large fraction of the membership may come more nearly under that vague designation of 'mining men,' that is, persons having an interest in the industry of mining, whether as shareholders, promoters, brokers, or journalists. Some of these are not even first cousins to a mining engineer, but they are worthy people and they derive much benefit from the association—to which they are welcome. But as long as the Institute is to be a society of mining engineers, the chiefs ought to be mining engineers also, always presuming that the men so selected are intended to be representative. Now, Mr. Ralston is a politician and a broker, not a mining engineer. As politician, he has been an effective State senator; as broker, his name appears in each issue of this journal on the page devoted to the mining market. We can readily believe that the good people in New York may have assumed that Mr. Ralston was a mining engineer because he is, or was, president of the California Miners' Association, but that assumption has a touch of humor. The gentleman was also in charge of mines at one time and then indeed he was a mining engineer, for a mining engineer is a man doing the work of a mining engineer. Whether he does it efficiently or inefficiently does not enter into the definition. Mr. Ralston is not *now* a mining engineer; he is a mining broker. That suffices. Finally, we are in a position to state the simple fact that Mr. Ralston depreciates and repudiates the mining engineer as a guide to the development and operation of mines. Moreover, if the American Institute is to stand for anything, it should have officers that stand for something. By what process, and by whom, was Mr. Ralston nominated?

The Washoe Decision.

On January 25 Judge Hunt, of the United States District Court, at Helena, Montana, handed down a decision denying the application of the farmers in the Deerlodge valley for the closure of the Washoe smelter. The Judge concludes that the loss to the general community arising from the closing of the smelting plant would be much greater than that sustained by the individuals making the complaint. He asks for further evidence in regard to mitigation of the nuisance due to fume, and he desires to be fully advised in regard thereto before making final disposition of the case. We rejoice in this decision and congratulate, first of all, the able technical men in charge of this great reduction works and, after them, the copper mining company which controls the Washoe plant. We also congratulate the people of Montana in being saved from a great blow to its basic industry, for a decision compelling the closing of the Washoe smelter would have been tantamount to a sentence of outlawry upon the metallurgical operations necessary to the extraction of copper from the ore deposits of the Butte district. It is high time that the public realized how far an unreasoning sentiment has been permitted to aid schemes of

The Washoe Concentrator and Smelter, Anaconda, Montana.

spoliation and blackmail. We have good reason to believe that the smelting companies are now fully awake to the danger of disregarding the public interest by carelessness in choosing smelter sites and reckless emission of fumes injurious to stock and to agriculture; every effort is being made to avoid infliction of injury, and if a similar solicitude had been evinced ten years ago, they would have been spared the unpleasant experience and the costly litigation that has crippled smelting operations in Utah, in California, and in Montana. We note with particular satisfaction that the decision in the Washoe case is based on equity. Before smelting was started at Anaconda there was no farming in the Deerlodge valley, only stock-raising; the smelter, and the mines contributory to it, created the local market for agricultural products, and stimulated the tilling of the ground. The campaign against the Anaconda company was due, in the first instance, to the effects of smoke distributed broadcast from a low chimney, which has since been replaced by a tall stack, so placed as to minimize harm by diluting the smoke. If the smelter, and with it the mines, were shut-down, the farms would become valueless. Widening the prospect, we find that not only the people of the Deerlodge valley, but the entire community living in the neighboring town of Butte would be deprived of a living should smelting, and with it mining, be stopped. Thus the decision is based on the greatest good to the greater number, and while it does not absolve the smelter management from every effort to mitigate a nuisance, it does place them in a position where they should be considered, industrially, not as enemies but as benefactors of the community.

Earthquake Forecasts.

In this issue we publish, by courtesy of the editor of *Science*, a lengthy abstract from an address on the above subject by the veteran geologist, Mr. G. K. Gilbert. No one is better qualified to offer an authoritative résumé of the tentative efforts to give a humanitarian value to the study of earthquakes. The test of a science is prediction; to that test seismology submits in a shamefaced manner, as one who has accomplished little but promises to do better if given an opportunity. Indeed, there is ample warrant for the sarcastic comment recently offered by Mr. T. A. Jaggar in *The Nation*, where he imagines an inhabitant of Mars, fresh from Professor Lowell's canals, dropping upon this planet and enquiring into the methods of earth study. The Martian is informed that we do many things skilfully; we weigh the stars and we foretell the movements of suns whose light has taken longer to reach us than the whole period of man's existence; at this our celestial visitor marvels greatly, but he is perplexed to learn that the earth-beings have failed to know and understand their terrestrial home, they have been so busy examining the heavenly roof of their habitation that they overlook the floor on which they stand. In truth, there is room for satire. Even our infant science of geology is so fully occupied in unraveling the history of the past that it has failed utterly in predicting the activities of the

future as they affect man. Only Italy and Japan have made a serious and systematic study of the dread unrest the expression of which is the terror that comes by night and the horror that darkens the day. The Japanese, living in a region particularly subject to earth tremors, have contributed fully a half of the real knowledge extant concerning earthquakes. It is time to take the matter seriously; no part of the earth's surface is absolutely immune from the danger, and while modern engineering has enabled man to build more strongly, the complexities of civilized life have added greatly to the horrors of the earthquake. When men lived under trees or in tents, the vibration of the ground might drive them mad, the rift in the surface might bury them, but they were spared the fire, the pestilence, and the manifold injuries due to falling walls, electric wires, burning gas, destruction of property, and unhinging of business. Man living in the state of nature suffered little from earthquakes such as worked untold harm to San Francisco, Valparaiso, Kingston, and Messina. Geologic evidence shows that in the remote past many portions of the earth's surface have been traversed by rifts causing a shifting of rocks accompanied by disturbances such as would have erased human beings anywhere near the line of movement, earthquakes as much severer than those recorded in written history as a railroad collision is more violent than the jostling of one man against another in a crowd. And yet the toll of human life during recent years has been terrible. Since January 1901 not less than 300,000 persons have been killed, that is, an average of 100 per day. It seems worth while to found a few chairs of seismology and endow a few observatories to study earth movements. Such an expenditure of money and brain-tissue is demanded in the interest of humanity. Nor would it be fruitless. There is hope of results. Mr. Gilbert cites several examples of forecasts made by scientific observers; to those quoted by him we may add the prediction by Mr. Frank A. Perret, an American vulcanologist, who nearly two years ago foretold the disaster in southern Italy. In November 1907 he stated in the *World's Work* that a great eruption of Mt. Etna was impending, and it is a fact that the Messina disaster came on the earthquake date, expressed by Mr. Perret as the "terrestrial maximum of gravitational stress," which was platted by him in his diagrams for 1908. This young American investigator devotes all his time to the special study of volcanoes and earthquakes, in a manner analogous to Pasteur's devotion to the study of bacteria. A few friends have contributed the funds necessary for Mr. Perret's investigations. Similar aid, but on a much larger scale, ought to be given by the governments of enlightened nations. The work requires observatories at many points, it needs delicate instruments and the preparation of detailed records; the large patience of the scientific enquirer and the intelligent persistence of the seeker after truth are wanted; but first money. Japan has led the way: the people deemed barbarians by the scum of Europe are the only nation that has tried systematically to study the phenomena that undermine the life of man.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

CHARLES W. MERRILL is at New York.

DUNCAN McVICHIE was at Tonopah lately.

H. W. TURNER is examining mines in Nevada.

CARNEY HARTLEY is examining mines in New Mexico.

MAX JUNGHANDEL, of Tonopah, is now at the Fairmont hotel.

E. S. PETTIS is with the Soledad Mining Co., at Mohave, California.

WILLIAM N. CUMMINGS, of Tucson, was in San Francisco for a few days.

A. D. GASSAWAY has left Berkeley for London, on his way to Siberia.

PHILIP WISEMAN is manager of the Ray copper mine, at Kelvin, Arizona.

A. B. ROGERS is superintendent of the North Star mine at Kofa, Arizona.

E. N. SKINNER is now advisory mining engineer to Trippe, Thompson & Company.

E. M. ROGERS is consulting engineer to the Golden Star Mines Co., at Kofa, Arizona.

R. B. HEGARDT is general manager for the Old Dominion Copper Co. at Globe, Arizona.

JOHN HAYS HAMMOND has been re-elected president of the Rocky Mountain Club, New York.

J. D. HUBBARD has been appointed metallurgist to the Oriental Consolidated, at Unsan, Korea.

ARTHUR LAKES has returned from California and has opened an office at 221 McPhee Bdg., Denver.

WILLIAM L. ROBERTSON, mill superintendent to the Montana Mining Co., is spending the winter at Salt Lake.

A. A. THOMSON is on his way from London to Kansanshi, in northern Rhodesia, in the service of the Tanganyika Concessions.

ARTHUR LAKES JR. has opened an office at 222 McPhee Bdg., Denver, and will make a specialty of placer mining and dredging.

C. G. PATTERSON has returned to San Francisco from Goldfield, where he has supervised the installation made by the Butters company at the mill of the Goldfield Consolidated Mining & Milling Company.

The next meeting of the Pacific Coast division of the Mining & Metallurgical Society of America is postponed from January 30 to February 13. The meeting and dinner will take place at the Pacific Union Club, those who are members of this club acting as hosts to those who are not. This meeting will be restricted to members of the Society who belong to the local division. It is expected that an important matter of policy will be decided.

Obituary.

THOMAS JONES died at the age of 74 from a stroke of apoplexy at his home in Neodesha, Kansas, on January 11. He began his career in the employ of Vivian & Sons., at Swansea, South Wales, and served with that firm for 15 years, after which he was associated with Siemens, assisting him in perfecting the open-hearth steel process, at Keinsdorf, Gratz, and Koenigshutte, in Germany. He then came to the United States and built a steel plant at Providence, Rhode Island. Later he became engaged in the zinc smelting business, and in this also he was one of the pioneers, building the first plants in Rhode Island, Virginia, Illinois, and Canada, the last mentioned being the works of the Canadian Metals Co., at Frank, Alberta, which was completed in 1907. He retired from active business a year ago, but still retained much of the strength and energy of a man in the prime of life. He leaves a wife and four sons, two of whom are engaged in mining.

General Mining News.

ARIZONA.

GILA COUNTY.

More detailed accounts of the recent strike made in the Gray mine of the United Globe, owned by the Old Dominion Copper Mining & Smelting Co., have come to hand. It was made in a winze below the 600-ft. level, 1000 ft. north of the Gray shaft, where 29 ft. of good sulphide was intersected by a cross-cut. It is reported that the whole 29 ft. of ore averages 5 to 6% copper. The same orebody has been opened on the 600-ft. level and to a less extent on the 700-ft. This discovery proves the existence of a big tonnage of ore.—On January 23, R. B. Hegardt, the superintendent of the Old Dominion Copper & Mining Co., posted a notice that the mines would be closed the next day and remain closed indefinitely. It was the first definite announcement of what had been feared for two or three days, following a controversy between the miners' union and the company as to the right of the walking delegate to visit the grounds. Every mine in the district, including the Miami, the Arizona Commercial, and the Globe Consolidated decided to support the Old Dominion in its position; and it was learned from reliable authority that the closing of the mines will be followed by the closing of the smelter in three or four days, when the supply of ore on hand will have been exhausted. It is locally believed that the presence in camp, and actions of one man alone is responsible for the shut-down that has paralyzed all business in Globe. This man is Albert Wills, walking delegate.

MOHAVE COUNTY.

The San Diego company which recently took over the Cruz mine near Yucca, has sent in supplies and expects to start work soon, sinking a shaft. Joe Kelsey and M. J. Ryan are watching the interests of the new owners.—T. J. Grant, who is in charge of the work for the Stewart-Warner Co., at Music Mtn., expects to have the hoist in working order within 10 days. Sinking will then be started. Carl Holtschue, of Goldfield, Nevada, is making an examination of the mine for the company.—Eighty-four oil location notices were received from the north part of the county this week. The first of the year witnessed the re-location of all the oil lands in the oil district along the Virgin river, both in Utah and Mohave county.—Mrs. E. B. Smith, of Hermosa Beach, California, has been looking over her mining interests in this county. She is a part owner in the Golconda and Alpha mines, in the Wallapai district. The Golconda mine is under bond to the Union Basin Mining Co. and is showing up excellent bodies of ore.

PIMA COUNTY.

The Fresno mines, in the Barbaquivari mountains, 75 miles from Tucson, have been sold to J. R. Clair and associates, of Orange, New Jersey, for \$200,000. The property was located 10 years ago, but has been worked only recently. There is said to be a vein 75 ft. wide opened to the 270-ft. level, all of which it will pay to work. E. T. Jones is in charge of the development work now under way.

CALIFORNIA.

ELDORADO COUNTY.

At Georgia Slide, where the several mines have been continuously operated for over 50 years, it is a common occurrence to strike a bunch of rich gravel which yields thousands of dollars, and this is reported to have occurred quite recently.—Seymour Hill, J. F. Owen, and Albert Shafsky will immediately install a 2-stamp mill at the Independence mine, in which a \$10,000 pocket was recently discovered. There is a small vein of rich quartz in the mine which they propose to take out and mill.—Word comes from Greenwood creek to the effect that a company which has been developing a group of claims on Greenwood creek near the Rogers ranch, has struck several veins of ore which are rich in gold, silver, and copper.

INYO COUNTY.

T. G. Crawford, of the Cashier mine at Harrisburg, has been working hard for the past two years to develop his property. Both by adit and shaft, orebodies have been met with, and Crawford is arranging for the construction of a mill. Eastern people agreed to put up a 10-stamp mill, provided Crawford could supply the requisite water-supply. This he has accomplished by purchasing from Warnebeck, of Ballarat, the water rights they held in Jail canyon, which gives a flow of eight miner's inches—more than sufficient for 10 stamps. He has arranged for this flow to come through the 10-in. pipe belonging to the Skidoo Mines Co., as their pipe passes through Harrisburg.

NEVADA COUNTY.

(Special Correspondence).—A rich shoot of ore was recently encountered near the 1000-ft. level in the Empire mine. The company has placed orders with a local foundry for two large plunger pumps. As soon as these have been installed sinking will be resumed.—A small force of men are working at the Midas. Some fair-grade ore is being developed.—Operations at the Hill mine have been abandoned for the winter owing to the large quantity of water encountered.—Operations at the Murchie mine have been suspended for an indefinite period.—Considerable work is going on at the Grover & Murphy property. A 2-compartment shaft is being sunk to cut an extension of the Mountaineer vein-system. The hoisting and pumping plant has been completed. Harry B. Gray is superintendent.—The Blue Lead gravel mine at Relief Hill has been bonded to James Graham, of Modesto, and J. V. Snyder, of Nevada City. It is intended to commence work at once.—District Attorney Ford has issued notice that all old shafts must be made secure in accordance with the law. Little attention has hitherto been paid to this matter here.—Within a few days a 200-gal. 2-step turbine pump will be installed at the Golden Gate mine. It will be operated by a 20-hp. electric motor.—Cross-cutting is progressing steadily at the LeDuc mine. It is expected to cut the vein within 300 ft. One shift is employed.—The Gold Flat, Pittsburg, Potosi and extensions of the Gold Flat and Pittsburg, have been consolidated and taken over by a company known as the Pittsburg Gold Flat Mines Co. The consolidation covers 107 acres of patented mineral land. All of these properties are well developed, and arrangements are being perfected by Mark B. Kerr, the manager, to begin work on a large scale. Grass Valley, January 25.

Every mine in the Grass Valley district has been much bothered by the long-continued rain storm; and especially those dependent on the electric current for pumping. For the voltage of the supply fell off, preventing the speeding up of the machinery to its full capacity. The water gained 100 ft. in the Idaho-Maryland mine, but the pumps are holding their own, and the manager anticipates no trouble, as all ore stoping is being done far above this level. At the Empire and North Star mines, men were laid off till the Colgate power plant was able to supply the full current, as all that came over the lines was required to keep the pumps running. Practically all the mines are at work again now, although the storm has been one of the fiercest for many years.

Tunis Young, vice-president of the Omega Placer Mining Co., has been making arrangements for the resumption of operations on the Omega gravel mine. Not much was done last year on account of a scarcity of water, but the recent heavy rains give assurance for an ample supply for the coming piping season. The mine is well equipped, with ample ditch capacity, and an electric plant for illumination. The restraining dam, on Scotchman's creek, retains a mile of storage ground. This summer a new outlet tunnel will be driven which will add another mile and a half of capacity for impounding the tailing.—The Blue Lead gravel mine has been bonded to James Graham, of Modesto, and James D. Snyder, of Nevada City. The present owners are not financially able to operate the property, and this is given as a reason for the deal now under way. The

Bloomfield ditch runs through the property, which contains about 670 acres. The channel is the same one that was worked in the Union mine adjoining the Blue Lead.

SAN BERNARDINO COUNTY.

A discovery of wulfenite, or lead molybdate, has recently been made by H. M. Benson and M. E. Stacey, near Nipton. The presence of this mineral has been known for some time, and the original source continuously sought. During the first week after the vein was discovered 16 tons of the ore were extracted.

SHASTA COUNTY.

A deed has been recorded conveying the Rough and Ready mine from E. W. Brackett to the Minnie-Shasta Mining Co. The mine is four miles west of Reading.—R. H. Stevens, who has been assayer at the Mammoth for some time, has resigned to accept a similar position with the United States Smelting & Refining Co.'s plant at Bingham Junction, Utah.

SISKIYOU COUNTY.

With the setting in of the inclement weather the Mammoth Copper Mining Co., of Kennett, has called in its diamond-drilling crew that has been for two months engaged in prospecting the grounds adjoining the holdings of the Sisson Exploration & Mining Co. No conclusion can be drawn, however, as to what the Kennett people may contemplate doing later.

COLORADO.

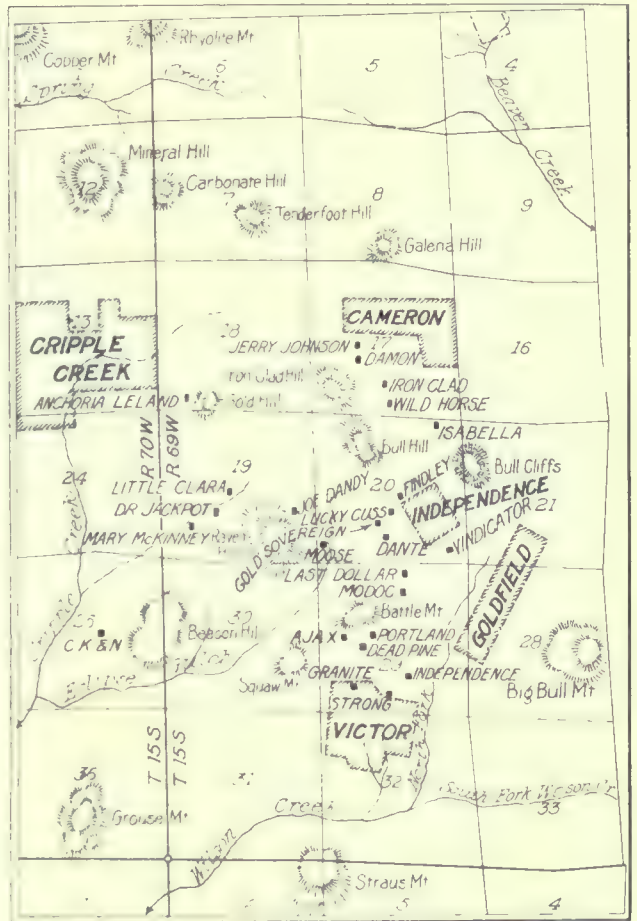

CHAFFEE COUNTY.

Christopher Kirsch, a veteran miner, prospector, and merchant of Granite, states that he is preparing to erect a mill on the Young America property on Yankee Blade hill, which he has been working for several years. He has about 15,000 tons of \$10 to \$15 ore on the dump, none of which could be shipped, as the charges for hauling are too great.—The little mining town of Winfield, south of Leadville, is quite excited over the discovery there of a large streak of gold ore in the Banker tunnel. According to information received from Winfield, a 6-in. vein of high-grade has been discovered which assays 6 oz. gold, 280 oz. silver, 15% copper, and 10% lead.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Waldorf Metals Co. has a force of men stoping the Wheeling vein, on a body of medium-grade ore which varies in width from 1 to 4 ft. Electric power is now being purchased and machine drills have been brought into use.—The Robert E. Lee adit on McClellan Mtn. has been driven over 600 ft. by F. Babcock, and should reach the Robert E. Lee vein within 150 ft. Oklahoma capitalists are financing the enterprise.—Work was resumed two weeks ago upon the Loop adit, the portal of which is situated near the high bridge of the C. & S. railway. The adit is in over 200 ft. and the South American vein will be reached within 300 ft. This vein yielded \$75,000 from the old workings. N. Anderson is manager.—H. Davenport has taken a lease on the third level of the Gold Dirt workings. A body of smelting ore has been exposed, from 18 in. to 2 ft. wide, and recent shipments netted returns of from 4 to 5 oz. gold per ton. There are 16 other sets of lessees at work on this property and heavy shipments are being sent out.—G. D. Parks, manager for the Crescent M. & L. Co., started the concentrating mill last week. This plant is situated below the dump of the New Boston mine and has been overhauled and remodeled. Tables and jigs have been installed, while electric power is being used to run the machinery. It is estimated that there is enough lead-zinc ore already developed to supply the mill for two years.—Work is being started on the Bellman mine, situated on Seaton Mtn. Operations will be carried on through the Newhouse adit.—A shipment of 26 tons of ore was made a few days ago from the Oxley lease at the Shafter mine and returns of 1.18 oz. gold and 10 oz. silver per ton were received. A streak of ore 20 in. wide is showing on the foot-wall, assaying 5 oz. gold per ton.—All the mills in the lower end of the county are running day and night. The Hudson plant is handling 100

tons of custom ore daily, and the manager, A. H. Roller, states that he has contracts that will insure the constant running of the mill during the year.—C. Hickman, who is leasing on the Little Mattie, is shipping an average of 60 tons of smelting ore each month that is worth from 2 to 3 oz. gold per ton.—The Sun and Moon, at Idaho Springs, is producing the heaviest tonnage of any mine in the district. From 4500 to 5000 tons of ore are being mined monthly, the greater part of the product being of milling grade. Contracts have been made with a number of mills for the treatment of the ore. R. C. Bonney is manager.—B. C. Catren is developing the Smuggler mine at Brown Mtn. Within another 30 days it is expected to have a crew of from 50 to 75 men at work. Driving east and west is to be started from the third, fourth, and fifth levels, while the shaft is to be sunk another 150 ft. Shipments of first-class ore are being made, worth about \$90 per ton silver and lead. A large amount of lead-zinc ore on

Map of Cripple Creek District.

the dumps will be treated at the Terrible mill as soon as there is sufficient water flowing through the pipe line.—The big Pelican mill, with a capacity of 250 tons per day, is to be started this week. The aerial tramway has been constructed to the old Pelican workings and the material on the dump is to be treated.

Georgetown, January 23.

GILPIN COUNTY.

Armfield & Co., who are working the Forks mine under lease from Senator H. M. Teller, are reported to have opened up a good-looking vein at a depth of about 250 ft., an assay of which showed \$150 per ton in gold, silver, and lead.—Two carloads of smelting ore were shipped from the East Leavenworth mine in the Russell district to the Argo smelter last week. The property is being operated under a lease by Hancock & Co., who have a shaft down about 300 ft.—Henry Peeck, of Central City, secured a contract yesterday for the erection of a new plant building 22 by 44 ft. in dimensions, and for the installation of a plant consisting of a 10-hp. horizontal engine and a 50-hp. horizontal boiler at the Oro mine in Chase Gulch. The

property is owned by Henry Bolthoff, of Denver, and is being worked under a lease by Manhire Bros., Gray Bros., John Park, and Stanley Harris, all of Central City.—There has been a report for several days past that the vein in the breast of the Newhouse tunnel is 11 or 12 ft. wide and that an assay of 17 oz. gold per ton has been obtained.

The Champion Mining & Milling Co. started its stamp-mill on North Beaver creek, and is handling ores from the Lone Star mine, where development has been kept up for some time. It is reported that the ore is amalgamating splendidly and a good clean-up may be expected. One shift is doing the work at present, but a night shift will shortly be put to work. About 15 lessees are at work on the Perigo property in the Independent district, and during the past week the mill was started on a 10-day run on ores taken from the different workings. Two cars of concentrate and one car of smelting ore are being shipped this week to the Argo plant. The improvements at the Smuggler mill in Moon gulch, consisting of a new engine and boiler, as well as additional tables for concentrating, are about completed. On account of the changes the mill has been shut-down for the past three weeks, but G. M. Ashmore, the manager, expects it to be running again very soon.

GUNNISON COUNTY.

Work has been resumed by the Ethel Gold Mining & Milling Co., in the Bowerman mining camp. The ore which it has uncovered gives hope that a mill may be erected when the snow clears away.

LAKE COUNTY.

The work of cutting the station at the 700-ft. level of the Helena shaft in Iowa gulch is now complete, and workmen are engaged in putting the new pump in position. It is expected that this will be completed during the present week, after which sinking will again be started.—There was more copper produced in the Leadville district in 1908 than in 1907, which at first seems paradoxical when the low price of that metal during last year is considered.

OURAY COUNTY.

The daily press announces that four men were killed and many had a narrow escape from death when an avalanche swept over the Camp Bird mine at Ouray, at a late hour on January 22.

SAN JUAN COUNTY.

It is understood that the Aspen mine will be re-opened at an early date and worked extensively. This is one of the Guggenheim properties, on Hazelton Mtn., near the Silver Lake mill. It is one of the old mines of the county and was a famous producer of the early days. The Aspen group embraces six or seven claims and is well developed. Two or three years ago the owners put the property in good condition. Now that the Silver Lake has closed down, that mill will be used to treat the Aspen ore. Morris Stockder will be in charge, as he has been for the past two years.

SUMMIT COUNTY.

Lennox & Giddings, of Colorado Springs, the owners of the Country Boy mine, have resumed work by driving an adit to cut the vein 200 ft. below the old workings. They ship that part of the ore which runs over 50% zinc.

TELLER COUNTY.

The leasing policy adopted by the Free Coinage Gold Mining Co. for several years past will remain in force during the present year, and few changes will be found among the lessees engaged in the development of this Bull hill estate. The leases expired by limitation on December 31, and renewals or new leases covering a 12 months period have been granted: the Pinto mine to Lowry & Rogers, last year's lessees; R. A. Young, T. L. Reid, L. A. Van Tilborg have secured a renewal of their lease on the Wilson; two sets of lessees, J. O. A. Carper and D. N. Mercer and associates, will operate different blocks on the Bison, and the Pueblo mine on Bull Cliffs. The royalties to be paid to the leasing company will be graded, ranging from 10% on low-grade milling ore to 35% on high-grade smelting ore.

—At the Vindicator shaft No. 2, Whitney, McMullen, and associates are maintaining steady production, and the lease is classed as a good profit. The output from the main shaft, operated on company account, will be somewhat curtailed for the present month, due to the construction of a fire-proof steel shaft-house and head-frame. The total production from the Vindicator company's mines for January, however, will not be much less than 2000 tons.—The head-frame formerly standing at the Geneva shaft on Gold Hill has been removed to the Half Moon mine on the same hill. Harrison & Shadomey are installing an electric hoist and will shortly resume underground work.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—The principal feature of this week's events in the Coeur d'Alene has been the starting of a suit for the foreclosure of a mortgage for \$150,000 by David M. Hyman, of New York, against the Frisco Mining Co., of which he is the president. It is alleged in the complaint that on October 1, 1907, the company, through its treasurer, J. L. Tilton, borrowed the sum of \$150,000 from Mr. Hyman, at the same time giving him a promissory note for that amount. This note was secured by a mortgage covering all of the company's equipment, mill, water rights, and holdings of all sorts. Mr. Hyman claims that no part of the note has been paid and petitions that the whole of the company's holdings be sold under sheriff's sale to satisfy the debt. It is generally believed that if the control of this company passes into the hands of Mr. Hyman a large force of men will be set to work and the mine again join the list of producers.—A special meeting of stockholders of the Idaho & Montana Mining Co. has been called for February 24, to consider the advisability of increasing the company's capitalization from \$100,000 to \$1,000,000. The increase will be obtained by changing the par value of the stock from ten cents to \$1 per share.—A report of the affairs of the company at the close of the year has been mailed to the stockholders of the Carney Copper Co. The report shows that during the year about 625 ft. of work was done on the mine, and that it is intended to offer a further block of treasury shares to the present stockholders at 7½c. per share.—A resumption of work has been made in the Hennessy-Burns mine in the Burke district and a force of men set to continue the drift. This has already been driven about 500 ft., but it is expected that 250 ft. of work will still have to be completed before the workings get under the good shipping ore reached by the upper adits.—The Surprise mine is again about to resume work. The mill at the property was completed just before the recent financial panic, and was forced to close down owing to the low prices prevailing in the metal markets.—At the annual meeting of stockholders of the Cassidy Gold Mining Co. held in Wallace, T. N. Barnard, of Wallace, was re-elected president and manager, and Miss Nellie J. Stockbridge, secretary and treasurer. During the past year about 500 ft. of work was done on a 6-ft. vein assaying from \$6 to \$7 per ton.—A strike of 13 in. of clean shipping galena has been made on the property of the Merrimac Mining Co. to the east of the Bunker Hill & Sullivan property. The ore was encountered about 50 ft. from the surface.—An electric plant capable of generating power for a hundred 16-cp. lamps is being installed on the property of the Hypotheek mine in the Kingston district. The plant will be run by the engine recently acquired by the company for its sawmill. A new hoist has also been installed at the mine and is giving every satisfaction.—At the annual meeting of stockholders of the Wallace Mining, Milling & Realty Co., held in Wallace, a new set of officers was elected, L. Dols retaining the office as president; Herman J. Rossi as treasurer, and Gary C. Burke as secretary. It was reported that during the year past about 250 ft. of work was done and arrangements for the resumption of development are being made.

Wallace, January 21.

Bear Top Mining Co. is considering the letting of a con-

tract for a 400-ft. raise to connect the No. 2 and No. 3 levels. There is plenty of ore in sight, and the mine will begin shipping as soon as the new road is ready. The property is equipped with a 100-ton concentrator.—Hecla mine at Burke, Idaho, produced 282,000 oz. of silver and 9,928,180 lb. of lead in 1908, as against 550,342 oz. of silver and 19,024,893 lb. of lead in 1907. The comparatively small output for the last year is due to the closing of the mine during the first five months on account of the market depression. The dividends were \$190,000 last year, as against \$520,000 in 1907. The total dividends to date are \$1,170,000.

NEVADA.

ESMERALDA COUNTY.

Six lessees are working on the Happy Hooligan claim. There is an incline shaft down 50 ft., with a cross-cut north 60 ft., at which point was opened a body of ore over 10 ft. wide, assaying \$8 per ton. The Truitt-Rawhide Mining & Leasing Co. has extended development on blocks 4 and 6. A winze is down 100 ft. from the 70-ft. level of shaft No. 3. Drifts are progressing both ways in ore which after screening over a 1-in. grizzly gives undersize assaying \$25 and oversize \$5 per ton. On the Miller lease is an incline shaft 65 ft. deep, in ore all the way, and a vertical shaft 130 ft. deep. The amount of milling ore on this lease, now proved, is very large.—The Rawhide Victor Mining & Leasing Co., on block 6 of the Happy Day claim, has a 12½-hp. gasoline hoist, head-frame, blacksmith shop, and a vertical shaft 200 ft. deep, with a cross-cut on the 125-ft. level, and some stoping done on the vein above this level. This vein is also cut by a cross-cut east from the 200-ft. level, with ore assaying \$15.—The Grutt Hill Coalition lease on block 7 of the Wild West has been worked intermittently, driving both ways on the vein opened up on the 107-ft. level.—The Rawhide, Grutt Hill, Truitt, and the Marigold lessees are working blocks 8 and 10 through a joint shaft. The shaft is 120 ft. deep. On the 50-ft. level is a cross-cut south.—The Grutt Hill Mint adjoins the Dayton & Toledo on the south on block 10. It is equipped with a 25-hp. hoist, head-frame, and blacksmith shop. An incline shaft 300 ft. deep has been sunk. At the time of the last report this shaft was down 140 ft., with drifts both ways at the 50 and 100-ft. levels. The ore-shoot developed in this lease was about 60 ft. long, and high-grade continued to the 250-ft. level, from which the ore has been stoped and shipped.—At the Original Rawhide, known as Kearns No. 1, the vertical shaft is down 150 ft., with 200 ft. of drifts and cross-cuts. The vein averages 2½ ft., with ore assaying \$22 per ton. Screenings shipped have returned \$100 per ton.—The Northern Consolidated Mines Co. owns 6 claims, the Alta Fraction, and the Morrissey lease, on blocks 1 and 2 of the Last Chance claim. The vertical shaft has been sunk 300 ft.; 350 ft. of cross-cutting and driving has been done at the 130-ft. level. The vein is 3 ft. wide, showing an average value of \$10 per ton.—The Consolidated Mines Co., of Rawhide, has sunk a vertical shaft 200 ft. on the Murray lease. The levels and other workings aggregate 2000 ft. The vein is nowhere less than 3 ft. wide, and in many places is 10 ft. The general average of assays gives \$20 per ton. Ore ready for mill now on the dump is estimated at 3500 tons. A 10-stamp mill will start operation within a few days.—The Czar G. M. & L. Co. has an incline down 60 ft., with 100 ft. of drifts, in 8 ft. of ore. Shipments of 8 carloads of ore have been made averaging \$107 per ton. There is also a vertical shaft down 90 ft., with 180 ft. of workings.—The McKinley-Hawkins lease has shipped 45 tons of ore averaging \$125 per ton. The shaft on this lease is 70 ft. deep, showing 33 ft. of low-grade ore, with bunches of high-grade. There is also a vertical shaft down 100 ft. 300 ft. distant from the first, the intention being to drive for the same orebody shown in the Czar shaft.—The Royal Mines Co. has an incline shaft down 440 ft., with a 110-ft. drift on the 65-ft. level, and a 40-ft. drift at 170 ft. The vein averages 3½ ft. wide, with an average assay value of \$15, while the ore in the bottom of the shaft assays \$23. From the results of development work in this mine sorted ore of a total value of \$13,000 has been shipped.

On his return to Goldfield from the annual meeting of the Goldfield Consolidated Mining Co., the manager, J. H. Mackenzie, made several statements as to the future policy of the company. That the Consolidated company would continue to operate the Combination mill, as there is an abundance of ore in the Combination mine to keep it going to full capacity. According to the agreement with the Combination Fraction Co. their ore would be treated at the new Consolidated mill when required, but the company has so much of its own that it cannot handle all its own product. It would therefore probably be necessary, within 8 or 10 months, to install additional stamps in the Consolidated company's new mill, as the ore reserves now blocked out in the mines are more than enough for the capacity of the plant at the present time.

HUMBOLDT COUNTY.

E. S. Chafey, of the Black Hole mine at Chafey, reports good progress at his mine. He has driven 1500 ft. of tunnels, shafts, and drifts; installed a 3000-ft. water-pipe line, made nearly a mile of wagon-road, installed a 40-hp. hoist, a boiler, and a 2-drill compressor. Then besides general improvements he has re-built the old mill and doubled its capacity.—The Cleghorn-Duke lessees of the Eureka Leas-

Block-holing.

ing Co. have recently purchased equipment which includes a 2¼-in. machine drill, an air-compressor, a blower, and two gasoline engines, one of 25 hp. and the other of 10 hp. It is now being hauled to the mine from Lovelock, their nearest railroad point. John Cleghorn is general manager.

LYON COUNTY.

The supply of electric power has been so intermittent during the past three weeks that the crews of the Yerington mines have been able to work only about half-time, and this half-time has been at odd times. The Truckee River Power Co., has been in trouble all fall and winter over low water and frigid weather. Now it is high water and warm weather.

STOREY COUNTY.

Virginia City's output for the week ending January 16 fell almost \$4000 below the last week's production, owing to lack of power and the consequent inability to hoist the ore. As usual, Ophir leads the Comstock producers, with \$15,950.

WHITE PINE COUNTY.

David Simmons, an employee of the Boston Ely Mining Co., was asphyxiated by gas in the mine while working on a lower level of the property.—Two converter shells have arrived at the Nevada smelter, and it is expected that the steel for the additions to the present converter building will arrive shortly. Steel for the fourth unit of the concentrator is now all at hand, and the erection of the additions will speedily be effected.

MISSOURI.

JASPER COUNTY.

(Special Correspondence.) A concentrating mill will be built in the spring upon a lease northwest of Neck City

which has been developed by Hill, Pugh & Springs. The 40-acre tract has been tested by six drill-holes which show good ore.—The erection of a 100-ton plant will be begun at once on the Microbe lease at Spring City. The company has developed the ground at the 116-ft. level, and drifts are being run in all directions from the shaft. This mine is the farthest east in the Spring City camp, and is beyond the supposed mineralized territory.—Underground development at the Plata mine in Spring City is being pushed in preparation for the possible erection of a milling plant. The Plata shaft is situated on the top of a hill, and hence the ore is found at a greater depth than in the other properties of the camp. Three drill-holes had been put down on the lease, and it is near one of these that the shaft is being sunk.—The output for this district has been greatly curtailed during the past fortnight by the heavy snow and blizzards. The gas supply was cut off from the mines, and altogether the whole mining industry was practically paralyzed for several days. Conditions are now again normal.—A contract has been let for a 300-ton plant on the lease operated by Barr, Gloeniger & Walsh. One feature of this plant will be the installation of a gravity tram between the second shaft and the mill. This has been tried with success at several properties in the district.—The old Bolby mine northeast of Webb City has been bought by George Ball and will be further developed by its new owner. It was formerly operated by Carterville men. The old plant will be removed and a new mill built in the near future.—The Nortonia, west of Joplin, will be deepened to penetrate the deposit below the 170-ft. level. During the underground development considerable improvement has been made in the mill. Additional equipment has been installed, including an air-compressor and a concentrating table.

Joplin, January 23.

NEWTON COUNTY.

The Granby Mining & Smelting Co. has completed a 150-ton mill at Granby, which has been designed especially to handle silicate ore. The trial run is to be made soon. It will handle about 150 tons of silicate, although in the Joplin district it would easily handle 300 tons of galena or blende. The lower capacity for silicate is due to the necessity of close sizing. A new crusher has been installed which dispenses with the ordinary rolls. The old plant has been used for many years, and was one of the earliest mills to be put up in the district.—A 150-ton tailing mill is being erected southwest of the Homestake mine by Eastern men to re-work the Homestake tailing pile.

LAWRENCE COUNTY.

In the east end of the Missouri camp there is at present a great deal of development work. Four shafts have recently been started on the Optimo lease, and it has been demonstrated that an ore deposit continues below their present workings.—A new shaft will be begun at once on the Church ground, which lies between the Boyd shafts and the Cameron. Excellent pay dirt was found in the drill-hole. The mine will be operated by the Golconda Mining Co.—In the Lone Pilgrim shaft, which has been in process of sinking for the past six months, a rich deposit was encountered this week, and appears to be as good as any found in the Sarcosie camp.—After long litigation the Lewellyn estate in the Belville camp is to be extensively developed, the land having been secured by Gundling & Maitland. This tract was mined more than eight years ago, and paid in royalties alone more than \$80,000. This property will be developed by Gundling & Maitland, as well as by sub-lessees who are already at work. The ore is handled at a 100-ton mill.

NEW MEXICO.

SANTA FE COUNTY.

The Boston Cerrillos Co. has partly cleaned up the shaft of the Cash Entry mine, and has pumped out the water down to the 300-ft. level. The shaft is 680 ft. deep, and others are being sunk. New machinery for treating the ore has been installed and consists of a Card concentrating table, eight sets of Hartz jigs, three sets of rolls, one large crusher, and a Huntington mill. The machinery is run by

a 160-hp. Corliss engine, and will have a capacity of 300 tons per 24 hours.

SOCORRO COUNTY.

The Socorro Mines Co., in the Mogollon Mtn., is erecting a 150-ton mill, a modern cyanide and concentrating plant, in connection with which they are now installing a 750-hp. hydro-electric plant at Whitewater, some three miles from the mill. The power pipe-line is 30 in. diam., while a 4-in. pipe will convey water for milling purposes. In times of scarcity of water, use will be made of two 375-hp. Babcock & Wilcox boilers and a steam engine for the generation of the power. Over a hundred men are employed on the construction of this plant, which will have a capacity of 150 tons per day.—The Enterprise Co. is re-building its cyanide mill as fast as material arrives, the former mill having been destroyed by fire a short time ago.

OKLAHOMA.

OTTAWA COUNTY.

(Special Correspondence).—A new mill has had its trial run this week in the Miami camp, and after a few days of needed adjustment the property will be ready to produce. The mill is the property of the Golden Hen, and is a first-class plant of 250 tons, every portion of the mill being new. The mill is just north of the Miami-Yankee, and is said to be operating upon the same ore deposit. There is rich ore on the dump which is ample to keep the mill running steadily.—The Swastika, a new mill in the southern end of the camp, is almost completed. It adjoins the Kenwood and King Jack, which have been producing for some time. During the building of the mill, underground work has been in progress at the 100-ft. level. It is thought that it will be sufficiently developed to supply the mill by the time it is completed.—Drilling operations are still being carried on at the John Countryman farm. The last hole encountered a steady flow of water, which with breakdowns in the machinery, have delayed the work. However, good ore has been found, showing both galena and zinc-blende.—A rich strike of galena and zinc-blende has been made at Seneca in the old Home Run mine, operated by McClughen & Evans. The ore occurs in a vein found at a depth of 40 to 60 ft. Five shafts have been sunk, finding galena in three, and zinc ore in a fourth.

Miami, January 23.

UTAH.

BEAVER COUNTY.

Samuel Newhouse is sufficiently satisfied with the performance of the new Fink smelting process as to make plans for the installation of a 300-ton unit at the Cactus mine. He believes that silicious ores will not be so necessary as under old conditions, and that slime and concentrate will be used to great advantage. To treat the above-mentioned capacity the cost of the plant should not exceed \$22,000.

JUAB COUNTY.

The Tintic Smelting company has made arrangements to secure water from the Gemini mine. The management of the smelter will use the Eureka Hill pipe-line, which extends from the Eureka Hill mine to a point a short distance from the smelter, whereby it will only be necessary to build a few hundred feet of line to connect the ends with the Gemini and with the smelter. The supply now used at the smelter comes from the Swansea mine, and while there is enough to supply the needs of the plant, the management decided that it would be best to have two independent water lines. So that with these two water lines and two separate electric lines, there is no danger of a shut-down at the Tintic smelter.

SALT LAKE COUNTY.

Samuel Treloar, manager for the Bingham-Butte Mining Co., is much gratified with the recent developments in the lower part of his mine, and intends to attempt to get the use of some of the custom mills of the Bingham camp; and failing in this, to erect a plant of his own.—The Government assay office in Salt Lake City has been thrown open for business.

Special Correspondence.

PHILIPPINE ISLANDS.

Gold Dredging on Paracale River.—New Zealand Capital in the Philippines.—San Mauricio and Tumbaga Mines.—Developments in Masbate.—Mancayan Copper.

Mining prospects in the Philippines continue to look well, but the long hoped-for mining boom which would cause a stampede of American miners and settlers into this country has not yet arrived, but it seems as if a better result may be attained by the slower influx of capital. In the last year more mining men have come to the islands, representing a greater amount of capital, than during any similar period since the American occupation. More gold bullion was produced last year than during any previous year on record, and, likely also, more than during any previous year in the history of the Philippines. More encouraging still is the increased amount of development work in progress, and the constant improvement and enlargement of the milling plants already erected.

In Ambos Camarines, at the site of the old and supposedly abandoned Spanish and English ventures of the early nineties, there is at present one gold dredge. It was brought from New Zealand and erected on the Paracale river in the early part of 1908. G. R. Fearby, a well known tin miner from Australia, who prospected the district for the New Zealand capitalists, was recently murdered by brigands in French Indo China while prospecting for tin deposits. The story is told that when Mr. Fearby reported his findings in the Camarines to Joseph Pearson, the head of the New Zealand syndicate, the latter shrewdly advised him to cut his figures in two; they seemed incredible to his associates. On the strength of Mr. Fearby's report an old dredge that had seen its best days in New Zealand, was sent out. Its capacity is only 300 yd. per day, and though it was shut down for repairs about seven weeks between May 1 and September 30, the output during this period has been about 2100 oz. gold, in addition to a large quantity of black sand containing 7 or 8 oz. per ton. Another New Zealand dredge is now being erected on the Paracale river, and a third one is being dismantled in Masbate, preparatory to being brought over to the Camarines. Systematic prospecting is being conducted on the Malaguit river about 11½ miles east of the Paracale river, and an understanding has been arrived at between the locators, which will result in new and larger dredging equipment being brought over from New Zealand.

The old San Mauricio and Tumbaga groups of quartz mines are being unwatered and re-timbered, preparatory to pushing development on these old properties. A representative of the concessionaries of the San Mauricio group is at present in the United States, trying to secure sufficient capital to renew operations. A Camarines Miners' Association has recently been organized, with A. J. MacDonald, an American, as president, and William Kane, from New Zealand, as vice-president.

Conditions in Masbate are beginning to improve once more. The Mt. Cogran and the Gold Bug mills remain shut down, but the dredge of the Lanang Mining Co., locally known as the Kimball dredge, is about to renew operations. This company, which is the successor of the old Philippine Dredging Co., was recently reorganized in Boston, and has finally cleared away all legal complications. The other Masbate dredge, locally known as the 'Gray dredge', which was brought over and erected here by the Oriental & Masbate Mining Co., at a cost of about \$70,000, is now being dismantled, preparatory to shipment to the Paracale river. The Eastern Mining Co. is continuing its prospecting and development work, but is milling no ore. Added interest has been given to the recently discovered deposits of lead and copper in central and southern Masbate by the arrival of two engineers representing separate mining syndicates in the United States. Both native copper and black sulphide ore have been found, and large veins of lead ore are indi-

cated. B. A. Green, formerly auditor of the Manila branch of J. G. White & Co., has gone to Masbate to take care of his interests in person. Edelmaier & Beasley, the two pioneers of Masbate, are reported to have struck a \$90 vein of gold ore, which they are preparing to mine in a small way and ship either to Australia or to Pacific Coast smelters.

The regular shipment of gold bullion from the Benguet mines, and the constantly increasing activity in development in this and the Camarines district, has been a source of great encouragement to prospectors and promoters in the Islands. Following a succession of mining fiascos, mining capital in the Philippine Islands had become scarce. Recently, however, two new companies were successfully

Philippine Islands.

floated to prospect and open new properties on the Antamok river. Capital for these enterprises was obtained partly from English firms in Shanghai and Hongkong, and partly from business men in Manila. There are at present 18 stamps dropping in the Benguet district, with two cyanide plants of a capacity of 50 tons each. More than half of the stamps are of the quadruple-discharge type. A notable feature of the operations of the two largest producers in Benguet, the Benguet Consolidated and the Bua Mining companies, is that, in spite of the fact that mining operations have been conducted at a profit to the above corporations, no dividends have yet been paid. All profits have been turned back to improve and enlarge the treatment-plants and to extend development of the ore reserves. The managers, more particularly of the Benguet Consolidated, which is the older of the two, deserve credit for their professional efficiency and for their good business judgment.

The copper mines in Mancayan and the gold mines in Snyoc, Lepanto Province, are still waiting the advent of a purchaser. It is estimated that the severe typhoons during the last rainy season caused washouts, caves, and general

damage to the extent of over ₧30,000. The prospectors, however, are showing a splendid spirit, and do not yield to discouragement. New workings are being started and old ones are being cleaned up. It is reported that an important German smelting firm expects to have its engineers report on the Mancayán copper property within a short time.

MEXICO.

Financial Surplus. — Mineral Output. — Precious Metal Exports. — Bank Statements. — Mine Developments in Zacualpam.

To anyone interested in Mexico, its industries and progress, the recent report of Finance Minister José Y Limantour to the Mexican Congress on the Republic's financial conditions cannot fail to be attractive. Mention was previously made in these letters of the splendid reserve accumulated during the last fiscal year, notwithstanding the general depression throughout the world. Although not equal to that of the preceding year, it was far in excess of previous surpluses. The reports now at hand show in almost all lines a material increase for the fiscal year 1907-08 over that of 1906-07, and strangely this has been more marked in the production of silver than in that of any other metal. The second on the list is gold. The production of silver amounted to ₧85,446,904, or 2,153,014 kg., as against ₧77,088,837, or 1,756,704 kg., for 1906-07, an increase of ₧8,358,077, or 396,310 kg.; and the gold output for 1907-08 was ₧38,096,661, or 28,572 kg., as against ₧36,563,898, or 27,423 kg., for the preceding year, an increase of ₧1,532,763, or 1149 kg. Of other mineral substances the total production amounted to:

Copper	₧24,800,000
Lead	5,400,000
Zinc	900,000
Coal	7,000,000
Oil	2,000,000
Miscellaneous	2,500,000
Total	₧42,600,000

This, with the gold and silver, makes a grand total for the mining industry of ₧166,143,000. Of the metal exports, gold amounted to ₧32,000,000, an increase of ₧8,000,000; silver, ₧93,000,000, a decrease of ₧7,000,000, due to the lessening of the exportation of coin silver to the amount of ₧14,000,000, whereas the exportation of silver in ores and precipitates increased to the amount of ₧7,000,000. Copper exports amount to ₧18,500,000, a decrease of ₧3,000,000; lead, ₧5,500,000, an increase of ₧2,000,000; and zinc but ₧1,000,000, or less than one-half that of the preceding year. The total exports of all products, mineral and others, amounted to ₧242,740,201, and the imports to ₧221,757,464, a decrease of ₧5,277,809 and ₧10,472,144, respectively, as compared with the previous year, yet, as may be seen from the above figures, the balance of trade was in favor of Mexico to the extent of about ₧21,000,000, and in excess of the preceding year by ₧5,000,000. The railroads of the Republic show gross earnings on passenger business of ₧16,436,498, an increase of 5.89%, and on freight ₧57,933,153, an increase of 9.59%. The banks at the close of business June 30, 1908, reported:

	Increase.
Total cash on hand.....	₧85,570,147 ₧10,322,947
Total deposits	407,139,179 7,880,832
Total capital and reserve..	222,054,382 12,058,451
Total assets and liabilities	756,522,308 32,758,622

It is certainly an unlooked for showing, when all conditions are taken into consideration. Some time ago attention was called to what might be the future expected for the camp of Zacualpám, State of Mexico, by reason of the approaching introduction of cheap electric power by the Temascaltepec Light & Power Co. from its hydro-electric power-plant 16 miles distant, and the expected has now been realized in the results at present existing in the said camp. The owners of ground in Zacualpám did not await the coming of cheap power, but took time by the forelock

and immediately began development of their properties, and now a number are reported in bonanza. The Seguranza (the old Coronas), controlled by George A. Waddell, of San Luis Potosí, had proved up its property, and work was started upon a 100-ton concentrating and cyanide mill, when the rainy season of last year made it advisable to suspend. Work on the mill has since been resumed, however, and it should be completed within the next four months. The Carboncillo has for some time been a producer, but developments within the last month have opened up rich ore and it is now stated to be in bonanza. The Olvidado, adjoining both the Carboncillo and the Seguranza, started operations six months ago on virgin ground, and is now in fine ore. Over 100 tons of high-grade ore has already been shipped, and the lower grade, amounting now to 10 tons per day, is being stored on the mine patio for treatment in the Seguranza mill. In the Yondese, H. L. Eisenhart has found rich ore, and in the tunnel on El Central ore was cut at 50 metres. The success of these properties, the coming of the electric power, and the approaching completion of the Seguranza mill, which will do some custom work for awhile, has given a great impetus to the district. Denouncements are being made in great numbers, and every one is sanguine of success. Even the Alacrán and the San Fernando, both of which are 'antiguas,' with many millions to their credit in the past, are said to again show ore equal to the bonanza days. Zacualpám is just now the bonanza camp. The Las Dos Estrellas at El Oro on January 1 declared a dividend of \$1 per share.

BUTTE, MONTANA.

Butte Copper Output. — Mine-Fire Control. — British Butte Dredge. — Butte & New York.

Copper producers are reluctantly admitting that the metal situation is disappointing and that there is a gradual accumulation of copper. Were business conditions satisfactory the surplus copper would be considered normal, but the improvement expected to follow the defeat of Bryan has not materialized. The Butte output is gradually increasing, though a considerable falling off will be noted for January because of the complete shut-down of the Boston & Montana mines for 11 days owing to the extreme cold, which interfered with ore transportation. The Butte Coalition Co. has increased its ore production to about 1300 tons per day. The North Butte Co. continues its output at 1400 tons per day, and all the mines of the Amalgamated Co., with the exception of the Anaconda, are producing a nearly normal quantity of ore. The Anaconda mine is worked only on the lower levels because of the fire prevailing on the levels above the 1600-ft., and the ore is hoisted through the St. Lawrence and Neversweat shafts. The fire levels in the Anaconda are being sealed and everything possible is being done to keep the gases out of other workings. That method has been successfully followed in the Minnie Healey by the Butte Coalition Co. The levels have been bulkheaded and new levels opened under the fire-zone through the new Tramway shaft, and about 60 ft. of ground is left as a barrier between the old levels and the first new one. The same fire trouble has existed in the Leonard and Colusa mines of the Boston & Montana Co. and the latter is following the example of the Butte Coalition and is opening new levels under the fire-zone. The British-Butte Mining Co. will start its gold-dredge on January 30. The dredge was built by the Risdon Iron Works of San Francisco at a cost of \$70,000. While the mining will for some time be confined to surface dredging, the company expects ultimately to hoist gravel from shafts. One has been sunk to a depth of 670 ft., from the bottom of which a bore-hole has been run 300 ft. more without encountering bedrock. A cross-cut has also been driven from the bottom of the shaft eastward to the rimrock of the gulch, a distance of 1080 ft., and from the end of that 50 ft. cross-cuts have been made north and south, encountering only placer gravel, the assay values of which vary from a few cents to \$3 and \$4 per

cubic yard. At the first annual meeting of the stockholders of this company held in Butte last week the following directors were elected: Manuel H. DeHora, Samuel J. Barker Jr., John N. Kirk, W. E. Ward, H. A. Frank, John F. Davies, and J. W. Murphy. The Butte & New York Copper Co., which is the holding company for the Butte-Milwaukee Co., of Butte, has elected the following board of directors: James A. Talbot, of Butte, Philip Lawrence, of Huron, Leo Schlessinger, Leopold Feist, B. Binnard, G. M. Mizesheimer, L. H. Halloway, F. B. Knight, A. E. Mittenhal, L. R. Thomas, and John Allan, of New York. Five hundred thousand dollars has been spent in the purchase of property, equipment, and development. The company owns the Pollock group of claims in the North Butte portion of the district. The shaft is 700 ft. deep and the veins give good copper assays at that depth.

TORONTO, CANADA.

Templeman Remains Minister of Mines. — Suffering at Gowganda. —

**First Ore Shipment. — Crown Reserve. — Nipissing Mine. —
Fraudulent Promoter Convicted.**

It has been decided that William Templeman will retain his position as Minister of Mines, endangered by his defeat at the last general election. It was necessary to secure another constituency, and this has been effected by the resignation of William Sloan, member for Comox-Atlin. His retention in office is mainly due to the strong support he received from the mining interests, which recognize that since his appointment the department has been put upon a better basis.

The new Gowganda silver-field continues to divide interest with Cobalt, and road construction is being pushed forward as the weather permits. Owing to the steady rush of prospectors, without experience in the hardships of a new country, considerable suffering has resulted. Harrowing accounts are received as to conditions in the Gowganda district; the hotels are full to overflowing, men are glad even for a chance to sleep on bare floors; some who have pushed farther afield to do snow-shoe staking are reduced to extremity by cold and privation, and some fatalities have resulted. The Provincial Government has selected about 1000 acres at the north end of Gowganda lake as a townsite. Squatters have been warned, and the lots will be sold by tender. The Mining Recorder at Elk Lake is overwhelmed with work, and owing to a lack of clerical help prospectors have to wait for indefinite periods before their claims can be recorded. The evidence at inquests over recent fatal accidents shows that the system of mine inspection is exceedingly perfunctory. It is asserted that this is not the fault of the inspector, but is due to his having entirely too large a field for one man to cover. The Otisse-Carrie mine, Silver Lake, is the first mine of the Montreal River district to make a shipment of ore. High-grade ore is being hauled to Charlton preparatory to loading a car.

The La Rose has proved the existence of an additional body of high-grade ore. Hitherto all ore for shipment has been taken out above the 110-ft. level. A find of 4000-oz. ore increases the depth of the reserves by 90 ft. The annual meeting of the Crown Reserve was held at Montreal on January 13, about 200 shareholders being present. The statement showed a surplus of \$317,117, after paying the January dividend of \$283,210. John Carson, the president, estimated that the output for the current year would amount to \$1,200,000, and that, allowing \$200,000 for operating expenses, there would be \$1,000,000 available for dividends. It is the intention of the directors to pay quarterly dividends at the rate of 24% per annum, with such bonuses as may be justified by earnings. At the Chambers-Ferland the new compressor-plant has been started for running three drills and one hoist. In the west cross-cut from the 80-ft. level of No. 2 shaft a vein 8 ft. wide consisting of calcite, cobalt, and galena was found 215 ft. from the shaft. The company has decided to use the diamond-drill extensively. During 1908 the Nipissing mine produced 7,062,527 lb. of ore, yielding 2,897,446 oz. silver, of a net value f. o. b.

Cobalt of \$1,384,447. The ore averaged 19c. per pound. At the Kendall shaft driving is being done both ways on the new cross-vein. The north vein has been faulted. At the south end it was split into three stringers, each averaging 1 in. wide, and assaying from 1500 to 2500 oz. The middle one is being followed. At the Meyer vein the west drift has been prepared for stoping. It is from 2 to 8 in. wide, averaging 3500 oz. silver, over a distance of 40 ft. The report of the Tretheway directors to be presented at the annual meeting January 27, covering a period of 16 months ending December 30, shows net proceeds from sales of ore of \$355,680. The total revenue was \$357,970, and expenditure \$147,446, leaving a profit of \$210,524. Dividends at the rate of 15% have been paid, amounting to \$141,817, a balance being carried forward to revenue account of \$68,706.

JUNEAU, ALASKA.

Rainy Hollow District. — Conrad Mine. — Alaska Mexican and Alaska United Reports.

The Alaska Iron Co. has recently paid the remaining \$20,000 of the purchase price of the Montana & Arizona claim, in the Rainy Hollow district, British Columbia. The company entered into a bond in August of last year, paying down \$5000 of the purchase price, which was \$25,000. Since that time the property has been prospected, both by cross-cutting and by core-drills, and the results have been highly satisfactory. The richer ore carries good quantities of copper and silver.

The ice on Lake Tagish being now strong enough to sustain large teams, the Conrad mine is shipping concentrate to the White Pass railroad at Caribou for final transfer to the smelter by way of Skagway. The distance from the mine to Caribou is 16 miles, but owing to the good condition of the ice, the 4-horse teams have no difficulty in hauling from 4 to 5 tons at a trip. The concentrator is working smoothly, and is treating from 40 to 60 tons per day. The water used in concentrating is pumped from a well situated beneath the floor of the mill, so that the plant may operate, irrespective of weather conditions.

The fiscal year of the Alaska Mexican G. M. Co. and the Alaska United G. M. Co., ended December 15 last, and the available figures for the year are as follows: The main inclined shaft of the Ready Bullion mine has been carried to a point 70 ft. below the 1650-ft. level, and the station and skip-chute station have been cut. The work of opening this level will be pushed as rapidly as possible. The development work of the 1500-ft. level is completed and stoping is in progress. The mill crushed 231,570 tons of ore, having an average assay value of \$2.70. An average of 10.37 machines was at work during the year, drilling 37.50 ft. and breaking 34.4 tons of ore per shift of 10 hours. A saving of 4512 tons of concentrate was made, or 1.95% of the ore milled. The average duty per stamp was 5.37 tons per 24 hr., and during the year 505 chrome shoes and 295 dies were used. The total amount of mercury fed was 46,175 oz., of which by far the larger amount was used inside the batteries. Of the total fed, 15,378 oz., or 33.30%, was lost.

The main shaft of the Mexican mine has been sunk to a point 1470 ft. below the surface. Stations and skip-chute stations have been cut at the 1210, 1320, and 1400-ft. levels. The 1400-ft. level is at the same depth as the 1450-ft. level of the Treadwell mine, and the two will be connected. From this mine 245,955 tons of ore was sent to the mills, 147,474 tons going to the Mexican mill of 120 stamps and 98,481 tons to the Seven Hundred mill of 100 stamps. The average assay value of the ore milled was \$3.02. The average number of machines at work in the mine during the year was 10.12. The average amount drilled per machine in a shift was 28.96 ft., and the average amount of ore broken per drill per shift was 29.30 tons. In the Mexican mill 3723 tons of concentrate was saved, or 1.54% of the total ore milled. The average duty per stamp per 24 hr. was 5.59 tons; and during the year 529 chrome-steel shoes and 270 cast-iron dies were used. The mercury fed was 61,008 oz.; of this amount 20,260, or 33.21%, was lost.

On the 1450-ft. level of the Treadwell mine the main cross-cut has reached the slate 'horse' dividing the north from the south orebodies. The ore exposed in the south orebody is 160 ft. wide, and up to the present time the length shown by the drifts is 300 ft., all in good ore. Sinking will be resumed shortly in this mine, either continuing the No. 2 shaft or starting a winze from the 1450-ft. level.

JOHANNESBURG, TRANSVAAL.

Status of Diamond Mining. — De Beers Consolidated, and Premier Diamond Mining Company.—Policies Compared.

So regular and detailed are the reports of Rand gold-mining companies, and with such thoroughness are their monthly yields and profits analyzed by the Chamber of Mines, that it is common in South Africa to regard the diamond mining companies as immoderately reticent. It is apparently hard for people, accustomed to the gold mining industry, which gives rise to no commercial competition, to realize the necessity for De Beers, the Premier, and other diamond producers, to closely preserve the secrets of administrative policy, and to ignore the demands of shareholders for information. The events of the past week, however, have thrown light upon the diamond mining situation, which, though not altogether cheerful, is welcome after the long period of doubt. The meeting of the De Beers Consolidated has been held in Kimberley, and its annual report issued, the premier company has also issued a yearly statement, and, in addition, invited the members of the Chemical, Metallurgical & Mining Society to visit the mine and observe the vigorous work of construction proceeding to provide the means for increasing the output.

The reports and programs of these giants of the diamond world present a striking contrast. The Kimberley corporation reviews the position with a caution expressive of mature experience; the tone of discretion and the greater forthrightness are suggestive of the mental attitude of middle age, while the Premier company takes up the bold devil-may-care position of the self-sufficient young man, confident of his strength and infallibility, who will not stoop to co-operation—who will fight his rivals and lose rather than resort to compromise.

The records of production for the year ended October 31 were published by the Premier D. M. Co. a short while ago, but financial details were only made available on December 19. Upon combining these two statements the following summary of the year's operations may be compiled: ground treated, 8,145,794 loads; diamonds won, 2,078,825 carats; yield per load, 0.25 carat; working costs, 1s. 10d. per load. (Load equals 16 cu. ft.) Comparing these figures with the returns for the previous year, it is to be noted that the increase is 1,607,000 loads, a fact forcibly expressive of the company's decision to entertain no proposals from Kimberley for a curtailment of operations during the period of depression. The value of the diamonds produced during the year is given as £1,536,000, equivalent to less than 15s. per carat, while the stock on hand in 1907 was worth £164,000. Actual sales, however, aggregate £1,104,000, leaving stones valued at £596,000 on hand. Of the realized profit (£358,000), £256,000 has been applied to capital expenditure, another indication of the company's headstrong policy. The reduction of working costs to 1s. 10d. per load is highly creditable to the technical administration. The decrease in yield per load is entirely due to natural considerations and cannot be criticized. The gradual fall in grade appears in the following table:

Year.	Yield	
	Loads	Carats
	Washed.	Produced.
1903	76,931	99,208
1904	939,265	749,643
1905	1,388,671	845,652
1906	2,988,471	899,746
1907	6,538,669	1,889,937
1908	8,145,794	2,078,825

In addition, the decrease in value of the product from between 22s. and 29s. per carat to 15s. per carat makes manifest the conditions prompting the directorate to rely upon quantity rather than quality for realizing aggregate profits in accordance with their ideas of the capabilities of the mine. It is clear that the producing capacity of the 'pipe' is enormous, but the absorbing capacity of the market is unhappily restricted. Whereas the Premier company has been dazzled by the former circumstance, the De Beers has been influenced to pursue a policy of prudence by consideration of the latter.

An examination of the report of the Kimberley corporation reveals a maintenance of value per load that is remarkable, and the apparent decrease is largely attributable to the fact that no diamonds were sold between February and June, the most critical period of depression, and that the stones won were taken into stock at the actual producing cost. On this basis of valuation, the diamonds won during the year are assessed at £3,354,000, with an expenditure of £2,630,000. This shows a decrease, as compared with the preceding year of unsurpassed prosperity, of £3,098,000 in revenue and £1,215,000 in expenditure. To achieve this reduction, it was necessary to close down the Dutoitspan and De Beers mines, while the Premier was forging ahead with its scheme of expansion in the northern colony. It has been pointed out again by the chairman of De Beers that such competition could not be withstood but for the difference in quality of the stones produced. Had the class of product been closely similar in the two centres, and had the Premier company, notwithstanding, pursued its own course regardless of De Beers, there would have been warfare with disastrous results. The De Beers Consolidated, however, has striven consistently to prevent a glut of diamonds. Hence the statement of diamond sales, accredited to each mine of the group, compares quite favorably with previous returns, as follows:

	1907.		1908.	
	Carats	Value	Carats	Value
	per	per	per	per
	Load.	Carat.	Load.	Carat.
	s.	d.	s.	d.
De Beers and Kimberley.	0.37	64 9.7	0.37	58 0.8
Wesselton	0.32	41 1.3	0.27	38 11.4
Bultfontein	0.32	43 6.3	0.32	41 4.8
Dutoitspan	0.24	79 6.8	0.23	74 5.1

These figures are for the year ended June 30, and prove conclusively that there has been no selling at 'bargain' prices, and the news now to hand that a powerful diamond syndicate is being formed, with Sir Julius Wernher and Solly Joel in control, gives assurance that no suicidal market developments will take place. So far as the fine-quality stones of De Beers are concerned (and the new Jagersfontein mine falls under the same influences), the supply will only meet the demand at prices roughly on a par with former standards. There are now other diamond mines in South Africa, notably the Voorspoed, which stand outside the two great groups, and which may eventually constitute a factor of importance in the trade, but during the present year at least, the situation will be completely dominated by the policies of the older producers. The reports of rich finds in Damaraland, southwest Africa, have lately been interpreted by sanguine supporters to herald the development of a new producing region of 'vast potentialities', but so far as reliable information in Johannesburg goes, the stones have been found only in shallow drifts, and have been almost exclusively of small size.

The extracts from the published reports discussed above indicate the policy recently adopted by the De Beers Consolidated, and also disclose the results obtained by the Premier during the year. At the Premier mines, the first two plants erected were for direct treatment, without weathering or crushing. Only the very friable surface material was amenable to direct washing. A new crushing and washing plant was put up. This commenced work in 1905. Its capacity is 20,000 loads per 24 hr. By the middle of 1909 an additional plant will be ready.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The Alaska-Treadwell mine consumes 21,600 cases of No. 1 and 21,204 cases of No. 2 dynamite each year. A case holds 50 pounds.

Mines are often spoiled by the attempt to get low costs, a big tonnage being obtained by free admixture of waste. Others suffer by the effort to lower the tailing to a degree more academic than commercial.

Location of quartz or lode claims may be made without restriction as to number by one individual. Such claims may be contiguous or non-contiguous; on the same lode or not; located on the same day or at any time; unless local district regulations or State statutes have otherwise provided.

Protective coating for cyanide vats should contain an asphalt base. Ordinary asphalt and coal tar, half and half, applied hot, is as good a coating as can be used. Two applications are necessary. The outside of the vat may be painted with the same mixture, or with ordinary paint containing a white lead 'body'.

Rectification of the boundary of a mining claim by an amended location, throwing open a strip of ground which had been comprised within the limits of the original location, leaves such strip available for location by any person, including the original locator. The new location covering such strip may be made immediately.

More men are killed in timbered than in un-timbered mines, for timbering indicates heavy ground, and the best of timbers may hold the ground without protecting the miner. In bad ground, timbers are apt to be a snare, for in most cases the machine-drill is set up beyond protection, and in hand-drilling the miner must work under overhanging rock.

Platinum at present is selling at \$24 per ounce for refined metal and \$20 for crude. Although the prices soared close to \$40 during the boom, it would be unsafe to estimate higher than \$18 or \$20. The great market for platinum is Paris, but buyers in New York will pay as good prices as the Parisian brokers.

Cyanide vats should not be constructed of green lumber. Unless it were all uniformly saturated, unequal shrinkage would result, and furthermore, the gradual shrinkage as the lumber seasons would cause trouble unless the work were done with even greater care than is necessary with dry stock. It would pay to make a kiln and dry the lumber locally, rather than employ it in a green state.

In re-tracing the lines of a mining claim recently it became necessary to determine which of a number of blazed trees was the original line-tree marked in 1882; the blazes having been partly covered by new

wood in every case. Sections about two inches cube were cut from a number of trees through the blazes and the new annual growth rings counted. When the tree thought to be on line was thus treated 24 rings were found above the blaze, which was taken as conclusive evidence that that was the right tree, since none of the others showed over 10 or 12 rings.

Trap is one of those general geological names used to signify an igneous rock of a basic, dark-colored, fine-grained character, such as diabase, dolerite, and well-crystallized basalt. Some mica rocks, occurring in dikes, are known as mica-traps. The use of the word is popular rather than strictly scientific. It is derived from the Swedish word *trappe*, meaning a step, relating to the peculiar step-like forms of certain volcanic flows.

Tungsten ore is mined extensively in the Nederland region, Boulder county, Colorado. The mineral is chiefly ferberite, which is essentially a tungstate of iron, containing about 61% tungstic oxide (WO_3), 20 of ferrous oxide (FeO), and from 6 to 16% silica, and a few per cent of alumina. Wolframite is a tungstate of iron and manganese, containing about 76% tungstic oxide. The tungsten ores rarely exist in a high state of purity, and silica is generally present in large amounts.

A mining claim, No. 1, is owned jointly by A and B. No. 2 and 3, adjoining No. 1, are under the exclusive ownership of B. Can B perform his yearly assessment work for claims No. 2 and 3 upon claim No. 1? The actual case is that a lease was given on claim No. 1, and \$300 worth of work done within the year. Can this apply to the other claims as well? In reply it may be said that the solution of the question is involved in considerable doubt. The Land Department would not accept such work for patent purposes. The Land Decisions have held that claims upon which 'group work' is performed must be contiguous, and that there must be unity of title in each claim included in the group. While the courts have shown greater liberality in ruling on the question of annual labor, there ought not to be any distinction in principle between the character of the work required for both purposes. It is true that one of the California State courts has recently intimated that, providing there is an understanding between owners of adjoining claims, work done entirely outside of such claims may be held to benefit them all, in spite of the absence of community of ownership. However, until this question has been passed on by the United States Supreme Court, it cannot be said to be placed beyond the realm of doubt. In the absence of a mutual understanding, a co-owner clearly cannot perform work on a claim held in common with another and credit it as assessment work on adjoining claims held in sole ownership. Business prudence would ordinarily dictate the policy of performing annual labor on each claim, where there is any question as to its applicability and sufficiency, rather than to be compelled later on to litigate an adverse title initiated upon the ground that the work had not been properly performed.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Cushioning Vibrations of Cam-Shafts.

The Editor:

Sir—I have read with interest Mr. Algernon Del Mar's article on this subject in your issue of even date. There is room for great improvement in this part of the mill, and Mr. Del Mar's article is helpful to the mill-man. The article states, however, that by this device the drop of the stamps can be changed by "taking out and replacing at will" pieces of belting. It is my opinion that this would occasion more loss of time than the old method of setting the tappets. To remove the cushion the cam-shaft would have to be shut down, whereas a first-class mill-man will set a tappet on one stem while the remaining four are running, thus continuing the crushing without loss of time.

THOS. N. MILLER.

San Francisco, December 26.

Forest Reserve and Mining.

The Editor:

Sir—I have been reading with pleasure and interest the letters published in your journal, concerning Forest Reserve matters.

Below are a few things observed by one that has been engaged in prospecting and mining for 18 years, during which time I have located, bought, patented, worked, and sold mining claims, and still have considerable mining interest in a National Forest. For the past two years I have been connected with the Forest Service.

The Forest Service can, and, I believe, will be made a benefit to the mining interests, but at present, in some cases, it is annoying to mining companies and prospectors. The privilege given, by the act of June 11, 1906, in regard to homesteads in Forest Reserves, may be used to blackmail honest mining enterprises. Any citizen may make application for examination and listing any possessory mining claim; the Forest Service is very slow to make these examinations, and then they are sometimes made by parties that are incompetent, through lack of experience in mining; pending these examinations, the miner cannot sell his claims, because of clouded title. The lode claims are also subject to examination before title can be perfected; these examinations are also sometimes made by parties that lack experience in mining. Still, if these examinations were made expeditiously by competent parties, it would be a benefit to mining companies and prospectors, as it would do away with an element of uncertainty that existed, even before the creation of the Forest Reserves.

There is no question in my mind but that the Forest Service is doing the public a great benefit in preventing the passing of title to land that should remain with the Government. The Forest Service is

helping mining companies and prospectors greatly by building trails, roads, and telephones, and last but not least, by preventing forest fires.

I am living in what is strictly a mining district, and the public sentiment is not strongly adverse to the Forest Service, in fact, many are outspoken in favor of it. There has been some friction caused by the arrogance of some Forest officers, together with the unreasonableness of some mine-operators. These things will be remedied in the future, but not without the help of criticism. The critics of the Forest Service are better friends of the Service than those that try to uphold some of the present methods.

A FOREST OFFICER.

Salt Lake, January 10.

Simplified Spelling.

The Editor:

Sir—I have noticed in your columns several sneering references to the simplified spelling movement; I think you are wrong, and I wish to protest against your attitude. I should like to know just what your attitude is. You evidently think that the English language needs improvement, for you are trying to force a new use of the word 'tailing' upon mining engineers. I, for one, have never heard it used in speech as you use it in your newspaper.

I hope further reflection will induce you to use your influence in favor of a more important linguistic reform, and that, as a first step, you will allow me to give your readers some account of the need of simplifying our spelling; because some of them, at least, have probably been misled by your jocose remarks.

Every student of English admits that our spelling is chaotic. There is not now, and there never has been, any standard spelling of English. Some of our erratic spelling, tho not 'made in Germany', is of German origin, and is due to German printers, who were brought to England to print our earliest books. Partly as a result of their ignorance of English "the spelling in the masterpieces of Elizabethan literature is a marvel of incompetency and orthographic recklessness."

That there is a vast waste of energy over disputed spellings can be seen by examining any recent dictionary. The Standard, for example, has a list of nearly 3000 words whose spelling is disputed. All the important dictionaries, and 57 philologists, have been consulted as to the spelling of these words. A rough estimate made by counting the references under several words, shows that about 200,000 opinions are recorded in this one list. But the great labor in making this list has settled nothing; it is merely a list of disputed spellings. It is certainly time that the English-speaking people should take up this question in earnest and establish some standard of spelling that the ordinary man can trust to when his spelling is questioned.

But much worse than the burdens cast upon the dictionary-makers are the weary hours spent by our children in trying to learn to spell—I say *trying* advisedly, for no one ever does learn to spell English

perfectly. So much of our children's time is taken up by spelling that they are said to be fully a year behind German children in their general knowledge. But even worse than the loss of time in trying to learn to spell is the demoralizing effect of the child's discovering that so important a subject as spelling is governed by no fixed laws. By the time he has learned the vagaries in the spelling of such words as *bough*, *plough*, *rough*, *tough*, *slough*, and *through*, his regard for law has received a severe twist, and he has acquired a "disbelief in learning and a total lack of confidence in inference."

It is to call attention to this stupid state of affairs, and to help remedy it, that the Simplified Spelling Board has been formed. This Board is a voluntary association of men who are specially interested in the question of spelling reform. It consisted when first formed (early in 1906) of 12 professors, 11 editors—including the editors of the *Century*, the *New English*, the *Standard*, *Webster's*, the *English Dialect*, and *Skeat's Etymological dictionaries* (practically all the important dictionaries of the language), and in addition to these editors and professors some 16 other prominent men, including Theodore Roosevelt, Mark Twain, and David Brewer. Among the professors I will only mention James W. Bright, Professor of English Literature in Johns Hopkins University; Richard Watson Gilder, editor of the *Century* magazine; Francis A. March, Professor of English in Lafayette College, and author of the *Thesaurus Dictionary of English*; Andrew D. White, formerly President of Cornell University; and last the benefactor who is furnishing \$15,000 annually for the expenses of the Board—Andrew Carnegie. It is self-evident that the opinion of such men as these, especially when they speak of their specialty, should be listened to with respect.

From the rabid attacks made on this Board one would think that they were doing something very revolutionary. As a matter of fact, all they have done is to call public attention to the need for a reform in our spelling, and to issue a list of 300 words, already spelt in several ways, and to advise that the simplest spelling of these words be followed. The Board has not suggested a single new spelling; the only word that could be called new in their list, is *thru* (for *through*), and this is the spelling adopted by the Philological Societies (American and British) in 1886, and by the National Educational Association in 1898, long before the Board was organized.

The Simplified Spelling Board has invited all interested persons to sign a card agreeing to use "some or all of the three hundred simplified spellings in their letters." Twenty thousand people had signed this agreement up to June 1908.

The League of Editors and Publishers now uses simplified spelling in more than three hundred newspapers and magazines, perhaps the most important of these being the *Literary Digest*. And, as is well-known, the spelling is used by some departments of the United States Government, and is considered important enough to have a special Government publication to itself. (This can be had from the Superintendent of Documents, Washington, for 25 cents.)

This movement to simplify English spelling finds supporters wherever the language is spoken or studied. In England, which is popularly supposed to be the home of conservatism, the campaign has been started by the formation of a society whose president, Walter W. Skeat, Professor of Anglo-Saxon in Cambridge, and author of '*An Etymological Dictionary*,' says, "is to consider carefully the whole subject of the history of our modern English spelling, with a view to the initiation of such a moderate system of small reforms as may seem to be generally advisable."

Among the vice-presidents of the English society are F. J. Furnivall, the former editor, and Sir J. A. H. Murray, the present editor of the *New English dictionary*. Both of these scholars are also members of the Simplified Spelling Board. The *New English dictionary*, now nearly completed, will be the largest and most scholarly dictionary ever published. It is based on 3,000,000 quotations, collected by 1300 readers, and studied by the greatest English scholars. The fact that these profound philologists support simplified spelling will greatly hasten its adoption. Because of the renown of the founders of this English society the English press has, for the most part, treated the question of simplified spelling with respect. The following remarks of Dr. Skeat seem to have been taken to heart by the journalists:

"We must enable the present race of newspaper contributors to become ashamed of discussing so confidently and so scornfully a subject which they only condemn because they do not understand it; and regarding which they employ unfair illustrations because they do not know that they are unintentionally becoming dishonest. Any man can make cheap fun of reasonable proposals, and can obviously do so the more easily if he unconsciously misunderstands and misinterprets the facts. The extent to which he is ignorant of the history of the discussion is daily being illustrated by the readiness with which he adduces, as if they were quite unanswerable, the stale objections that have been refuted many times and oft. A critic would do well, in conformity with common decency and fairness, to ask himself the question whether he knows enough of the matter to entitle him to an opinion. Let him first of all learn the right answers to a few elementary questions. Why, for example, do we spell *oak* with *oa*, but *spoke* with an *o* and a final *e*? How came *ou* to denote the diphthongal sound which is heard in the word *house*, while the same sound is expressed by *au* in German? How came the same symbol *ou* to denote the *ou* of *soup*? How is it that the sound of *a* in *cake* can be represented in at least twenty-one different ways, and the sound *ee* in *feet* in twenty-four different ways?"

It is of interest to note that this simplifying of our spelling is but part of a world-wide and inevitable reform. Great changes have already been made in German spelling; French spelling is being reformed by the French government, acting thru the Academy; Holland is changing her spelling; Russia is discussing the dropping of useless letters that will save a twelfth of her printing-bill.

Objectors to reformed spelling say that we ought to preserve inviolate the spelling of our ancestors. Here is an extract from Rider Haggard's 'King Solomon's Mines,' which some one has put into "Elizabethan orthography":

"We got up and drest ourselves for the fray, each putting on our chayne-armour shirte, for which at the present juncture we felt exceedingly thankful. Syr Henrie went the whole hogge about the matter, and drest himselfe like a native warrior. 'When you are in Kukuanaland, doe as the Kuku-anas doe,' he remarked, as he drew the shining steele over his brode showlders, which it fitted like a glove. Nor did he stop there. At his request, Infadoos had provided him with a compleate sette of warre uniform. Round his throte he fastened the libbard-skyne cloke of a commanding officer, worn onlie by generalls of his ranke, and round his center a magnificent moocha of white oxetayles. A paire of sandals, a leggett of goates hayr, a heuie battleaxe, with a rhinoceros-horne handle, a round iron sheelde, couered with white ox-hyde, and the regulation number of tollas, or throwinge kniues, made up his equipment, to which, howeuer, he added his reuoluer. The dresse was, no dout, a sauage one, but I am bounde to saye I neuer saw a finer sight than Syr Henrie Curtis presented in this guyse. . . ."

We have certainly simplified the spelling since those days, and the end is not yet.

Other objectors say that simplified spelling will so alter our words that their etymology cannot be traced. The ordinary user of language cares as little for the origin of the words he uses as does the user of a fountain-pen care for the name of the forest where the rubber trees grew that supplied the rubber of which it is made. One who wishes to study etymology can find plenty of material in the works already published, and works published after today are of no use to the searcher for the etymology of a word which already exists.

English is now the most widely used, and most important commercial language. A simplification of its spelling will make it easier for foreigners to learn, and thus aid it in its struggle for supremacy as a world-language. As pointed out by the veteran publisher, Henry Holt, a simplified spelling will save millions of dollars annually by lessening the work of authors, compositors, proof-readers, and printers. A greater boon than any mere money-saving will be in the lessening of the task of our school-children, and the showing them that law and order rule English spelling.

While I personally think that the adoption of a scientific alphabet is needed to finally settle this question, I feel that the reforming of our spelling can safely be left in the hands of our great scholars. But, surely, the duty of every man is to help this work to the extent of his powers and neither should he sit in Buddha-like immobility with folded hands, nor should he follow the advice of another Oriental religious leader, the Chinese sage, Lao Tzu, and "do nothing and all things will be done." But either of these two attitudes is better than sitting on the fence and throwing stones at the procession as it

moves on its way toward the goal of a scientific spelling of English.

WILLIAM H. SHOCKLEY.

San Francisco, January 15.

Note. Most of the information in this letter has come from the publications of the Simplified Spelling Board, No. 1 Madison avenue, New York. These are sent to anyone who asks for them. The remarks on the English movement are taken from the Literary Digest, of December 5, 1908.

[In courtesy to Mr. Shockley we have not edited the 'reformed' spelling used by him in a few cases; in courtesy to the reader we shall not follow this lengthy communication with another, for we discussed the subject thoughtfully and carefully in our issue of September 29, 1906, to which Mr. Shockley makes no reference. He was probably examining a mine in the wilderness and happened not to see that number. We are glad to give space to views so opposite to our own.—EDITOR.]

Progress in Cyanidation.

The Editor:

Sir—I had the pleasure of reading in your issue of January 2 the article by Alfred James upon the 'Progress of Cyanidation' during the last year, and I find myself obliged to make a correction. It is true that until the month of June last we had a ball-mill at work with its grinding pan for dry-grinding, but the class of ore which this mill ground was precisely like that ground in the Chilean mills. It is an ordinary quartz ore, the only notable difference in the two cases being in the size of the feed; for while we fed ore from 3 to 4 in. diam. into the ball-mill, the size going to the Chileans was 1½ in. as a maximum, that being most appropriate for mills of that type. Neither did we feed soft ore to the Chilean mills.

FRANCISCO NARVAEZ.

Pachuca, Mexico, January 11.

Protection of Investors.

The Editor:

Sir—In your issue of January 9, on page 83, an error of one word in the first sentence of my communication to the San Francisco section of the Mining & Metallurgical Society completely changes the meaning. It is there stated that "Itemizing is a ready means of observing results." As originally written, the word 'obscuring' was used in place of 'observing'.

I regret to have to add that the blunder occurred in my office, as I discover that the carbon copy of the typewritten article shows that you have followed copy correctly.

THEO. B. COMSTOCK.

Los Angeles, January 11.

A tax of one cent per ton on bituminous coal, to create a fund for the relief of sufferers from coal-mine accidents, was proposed by the American Mining Congress at its meeting at Pittsburg in December last. As the output of bituminous coal in America is about 380 million tons, such a tax would produce \$3,800,000 per annum.

EARTHQUAKE FORECASTS.

By G. K. GILBERT.

*There was a time when the weather belonged to the gods. Storms and drought were inflicted on man in punishment or for vengeance, man strove to avert them by sacrifice or prayer, and the priest was his intercessor. Now the weather belongs to nature, and the priestly robe has fallen on the Weather Bureau. Man's new agent, however, is not an intercessor; he does nothing to placate; he makes no attempt to control the course of nature; but inspired by science he foretells the coming changes so that his lay client may take warning and be prepared. The crops are harvested before the rain, the herds escape from the lowlands before the flood, the ships reach harbor before the gale; and man chants a hymn of praise to science.

There was a time when the earthquake was equally enveloped in mystery, and was forecast in the enigmatic phrases of the astrologer and oracle; and now that it too has passed from the shadow of the occult to the light of knowledge, the people of the civilized earth would be glad to know whether the time has yet come for a scientific forecast of the impending tremor.

Next to verity, the factors which give value to an earthquake prediction are definiteness as to time and place. If the geologist Whitney, in warning San Franciscans forty years ago that their city would suffer by earthquake, had been able to specify the year 1906, and to convince them that he had warrant for his prophecy, the shock, when it came, would have been a phenomenon only and not a catastrophe. If any of those mysterious oracles who were said to have predicted earth convulsions in 1906 had named San Francisco, and told their reasons, the course of history might have been different.

Let us consider first the possibility of scientific forecast as to place, and in so doing let us assume the point of view of the resident. The factor in which he is personally interested is the factor of danger—danger to life, danger to property, danger to the present generation. Except as a matter of curiosity, he is not concerned with faint tremors and minor shocks, nor with violent shocks likely to come after centuries of immunity. It will be convenient to embody our point of view in a concise term, and the adjective 'mallooseismic' will be used to designate localities likely to be visited several times in a century by earthquakes of destructive violence.

Experience.—The most important of all bases for the indication of earthquake localities is experience. Where tremors have been frequent in the past, there they are to be expected in the future. This premise is founded on our confidence in the continuity of the great processes concerned in the evolution of the earth.

Other bases for forecast are connected with our conceptions as to the origin of earthquakes. The the-

ory of earthquakes now generally accepted ascribes them to the sudden breaking or slipping of rocks previously in a condition of shearing strain. Exception should probably be made of some of the shocks accompanying volcanic eruptions, but volcanic shocks constitute a class by themselves, to which it is not important to extend the present discussion. In non-volcanic, or ordinary, examples it is believed that strains arise in connection with changes exhibited superficially in the deformation of the surface. Fracture occurs when and where the internal stress exceeds the strength of the rock, and a fault results. Slipping takes place when the stress along the plane of a pre-existent fault exceeds the force of adhesion. In either case it is the instantaneous character of the separation which occasions the jar.

Bold and High Ranges.—It was pointed out by Powell that, because erosion is greatly stimulated by altitude and high declivity, lofty mountains must be regarded as young; and under the principle of continuity young mountains created by uplift are presumably still growing. They are, therefore, phenomena of diastrophic activity and presumably belong to mallooseismic districts. The conspicuous example is Mt. St. Elias, which rises boldly 20,000 feet from its base, which was shown by Russell to have continued its growth during the life of the existing marine fauna, and which recently has been signalized by earthquakes of the first class.

Fault Scarps.—Along the bases of block mountains the lines of their limiting faults are sometimes marked by fresh scarps demonstrating recent increase of uplift. In the Great Basin these scarps traverse the alluvium of the piedmont slopes, a surface of such simple type that their presence or absence can be observed with confidence. Their presence suggests diastrophic activity, and the suggestion is strengthened when their relation to phenomena of weathering and erosion is such as to show that they were produced by a series of recent uplifts instead of one only.

Rifts.—A third physiographic criterion is illustrated in California, and was brought to general attention by the San Francisco earthquake. The slip causing that shock occurred on the plane of a fault which outcrops at the surface and has been traced for hundreds of miles. The attitude of the plane is vertical, but the displacement along it was horizontal; and there is reason to think that earlier movements on the same plane were horizontal also, for the fault does not separate a ridge of uplift from a valley of depression but traverses both valleys and mountains. At all points it is included within a belt of peculiar topographic habit, which the investigating geologists have designated as 'the rift'. Within this belt, which ranges in width from a fraction of a mile to several miles, are numerous ridges and troughs, long or short, level or inclined, and approximately parallel to the trend of the belt. Each of these represents a dislocated tectonic block, and the dislocation is of so recent date that the disturbed drainage has made little progress toward the restoration of normal conditions. Lakelets are numerous, and streams wander irregularly. Other belts of the same

*Abstracted from advance proofs of a presidential address to the American Association of Geographers, read at Baltimore, January 1, 1909. By courtesy of the author.

character have already been found in California,* and their discovery elsewhere may confidently be expected.

Rift topography appears to be the surface expression of a species of repetitive horizontal faulting, just as the fault-scarp is the surface expression of vertical faulting. The features of the San Andreas rift—the one associated with the San Francisco earthquake—were neither created nor greatly modified at the time of that shock, but such modifications as were made were of such character as to accentuate and perpetuate the peculiarities of the belt. The belt itself would be the natural result of a long series of such events, succeeding one another with such rapidity as to dominate minor aqueous agencies in the modeling of the surface.

Geologic Formation.—Fault-scarps and rift-belts serve to indicate some of the foci of past and future earthquakes. Other foci lie wholly within the earth's crust. Whether the rupture occurs above or below, its jar is propagated through the crust in all directions and affects a large area of the surface. Within this area the intensity of the shock varies primarily with distance from the origin, but it varies also with the character of the geologic formation at the point of emergence. The variation with formation has less range than the variation with distance, but is not less important to the resident and the sojourner, the architect and the engineer—that is to say, it is equally important in forecasting areas of dangerous energy. The portion of San Francisco most intensely racked by the shock of 1906 stood farther from the fault line than the portion least affected, but it stood on less coherent soil.

Turning now to the time factor in forecasting, and retaining the point of view which emphasizes the element of danger, let us inquire what methods are available for the prediction of the time of occurrence of a destructive earthquake at a given locality or in a given district.

Rhythm.—Because we are surrounded by and immersed in the rhythms of art and nature, and because the earthquake is a recurrent phenomenon, it is easy to infer that the interval between the last shock and the next will be similar to that between the last and its predecessor. Reasoning of this general tenor probably underlies the greater number of lay forecasts, and is in particular responsible for the widespread popular belief that a place recently devastated is *ipso facto* immune for several decades, or at

least for several years. A similar belief prevalent among men of science has a slightly different origin, but is even more strongly held; and there is little exaggeration in saying that our guild recognize it as a duty, when the terror-stricken inhabitants of a racked and ruined city seek safety in the open spaces, to assure them that the danger is past and urge them to return to their homes. Now, it is not at all true that either the great shocks or the small shocks are separated one from another by regular or approximately regular intervals; and it is not at all true that immediate danger is past when a great shock has wrought its havoc; and yet I am prone to believe that the rhythmic principle does hold place in the mechanics of earthquakes.

The United States has one well known mallooseismic district, a district including central and southern California, with areas in Mexico and the Pacific Ocean, and possibly extending northward. Alaska also contains a district, and there may be a third in Utah. Since the beginning of the last century Alaska has experienced at least nine shocks of destructive rank; but the record is fragmentary. For the California district eleven are listed, within the same period. To these we may tentatively add the Oregon or Klamath earthquake of 1867 and the Sonora and Arizona earthquake of 1887, raising the number to thirteen. In other parts of the United States were the New Madrid (1811-12), the Charleston (1886), and a relatively weak but probably destructive shock in the New Madrid region in 1865.

The average interval between the individuals of the California series was nine years, and the separate intervals, in order, were: 12, 24, 3, 18, 8, 2, 1, 4, 15, 5, 6, and 8 years. As the centres of disturbance were scattered through the whole district and the areas of dangerous violence were of moderate dimensions, the danger record for any single locality was smaller, and the intervals correspondingly larger. In San Francisco, for instance, the last five destructive shocks have been separated by intervals of 26, 3, 30, and 8 years.

The single element of order which unquestionably belongs to the sequence of quakings is implied by the term 'after-shock'. Every great shock is followed by a train of minor shocks, the length of the train being roughly proportional to the magnitude of the initial shock, and the average strength and frequency of the shocks diminishing with the lapse of time. Usually also the great shock is preceded by faint tremors, or by a few small shocks. The prelude, the great shock, and the train of after-shocks, together constitute a typical seismic event, and if their sequence could be absolutely depended on, the terror of the great shock might rationally be palliated by the thought that the worst is over. But unfortunately there are exceptions, and the character of the exceptions is not reassuring. Occasionally the prelude includes a shock of great power, and occasionally the train of after-shocks, instead of being wholly subordinate in intensity, includes one or more major shocks, rivaling the initial shock in violence. Of the 25 American examples, 14 were normal and 2 abnormal, the others remaining unclassified because

*The only rift-belt besides the Andreas which has yet been traced for any distance is one which follows in a general way the western base of the Berkeley hills. In the vicinity of Oakland its position is indicated by a trough among the lower hills two or three miles back from the piedmont plain. At Haywards it coincides with the western base of the hills, and at Irvington, with the western base of a projecting spur. In Berkeley also its line follows the base of the hills, but a little northward it climbs to the summit of the first ridge. The principal fault occasioning the earthquake of 1868 was in this rift-belt, running from Haywards southward, and it is probable that some of the earlier recorded earthquakes were associated with the same belt. The fault of 1868 is described, and the rift belt is mentioned, in the 'Report of the California Earthquake Commission,' Vol. I, Part II, pp. 434-5 and 447.

too little is known of them. It is possibly significant that the two abnormal earthquakes were of exceptional power, the New Madrid heading the list for the United States, and the Yakutat, of Alaska, being of the same order of magnitude.

Alternation.—The principle of alternation in the occurrence of earthquakes has already been touched. When a large amount of stored energy has been discharged in the production of a great earthquake and its after-shocks, it would seem theoretically that the next great seismic event was more likely to occur at some other place, and that successive great events would be distributed with a sort of alternation through the district. This hypothesis I used twenty-five years ago in predicting that the next slip on the fault at the base of the Wasatch range, instead of occurring in the locality of the last previous slip, would take place at a different point; and it has been more recently applied by Omori, Hayes, and Lawson in forecasting earthquakes on the western coast of the two Americas. These geographers agree in regarding the entire coast either as a single seismic district or as a portion of a greater district, in which there is interdependence of parts. Omori pointed out that in the period of six years from 1899 to 1905 there were extensive disturbances in Alaska, Mexico, Central America, Colombia, and Ecuador; he stated that the gap thus left between Alaska and Mexico had led him to anticipate an early rupture in that tract of coast; and suggested, after his first anticipation had been realized by the San Francisco earthquake, that the next disturbance might be south of the equator—where the Valparaiso earthquake soon afterward occurred. Hayes, after the San Francisco and Valparaiso earthquakes, suggested Mexico as a probable locality for the next rupture; and after the earthquake which devastated the State of Guerrero, in southern Mexico, made a similar suggestion as to Colombia. Lawson mentioned breaks in the continuity of recent demonstrations, between the southern part of California and Central America, and between the northern part of California and Alaska, and suggested the probability of early visitations in Mexico and the Oregon-Washington region. In this forecast he anticipated by a few weeks the Guerrero earthquake. Omori went farther and expressed the opinion that the Valparaiso earthquake was the final term of a series, and that the whole Pacific coast of America would be exempt for a time from *great* seismic activity. He expected for San Francisco a period of immunity of thirty to fifty years, and for coastal regions from Alaska to Ecuador of twenty to thirty years.

It will be observed that this idea of a series, breaking on the American coast in the course of a few years, and followed by a comparatively long interval before the arrival of another series, an idea apparently shared by Hayes and Lawson, combines rhythm with alternation in the theory of forecasting.

Prediction and verification are the test of hypothesis, and this group of predictions, embodying the diverse views of independent investigators, who approach the subject from both seismologic and geo-

logic sides, constitute a valuable contribution to seismic forecasting.

Trigger.—The third general principle applicable to prediction is that of the trigger, or the straw that broke the camel's back. As the growing earth stress little by little approaches the limit of the resisting force, there is a critical period during which a relatively small additional stress arising from some other source may precipitate the catastrophe.

The principal known causes of periodic variation of stress are bodily tides of the earth; oceanic tides, which alternately load and unload the sea-bed near the shore; the winter load of snow on parts of the land; annual and diurnal variations of atmospheric pressure; diurnal variations of barometric gradient; and the wandering of the earth's axis of rotation. The relative importance of the several influences can not yet be indicated, but it is known that their absolute importance is not the same in all places. Three belong to the coastal belts, two to the land; and two belong to land and sea, but vary in latitude. Their relative importance in any particular locality may depend also on the direction of the slowly growing tectonic stress of the crust; for in order to be effective the temporary or adventitious stresses must be of such character as to augment the tectonic stresses. Let me illustrate this point.

The tidal sway of an oceanic basin raises and lowers the surface very little where the water is deep, but has a much greater effect on the shoals bordering coasts. The strip of sea-bed following the coast is subjected twice a day to the addition of a heavy load of water, and in the intervening hours is relieved of pressure by the same amount. On the seaward side of the strip there is a gradual change in pressure, and on the landward side, just at the water's edge, an abrupt change; and these pressure differences cause strains and stresses in the crust beneath. The directions of the induced strains lie in vertical planes at right angles to the coast, and are competent to increase or diminish tectonic stresses having similar directions. On the coast of Alaska near Mt. St. Elias the tectonic changes in progress include an uplift of mountains parallel to the coast, and the main tectonic stresses may be assumed to lie in vertical planes normal to the coast; so that here the oceanic tides are competent to precipitate earthquakes. But on the California coast near San Francisco, where the directions of the main tectonic stresses are horizontal and are approximately parallel to the coast, the stresses from oceanic tides may be ineffective. On the other hand, the stresses created in the crust by the shifting of the axis of rotation are probably better calculated to augment tectonic stresses at San Francisco than at Mt. St. Elias.

The most potent of all precipitants of earthquakes is also useless to the forecaster, because its action is unforeseen. It is the earthquake wave emanating from a near by focus. The response to such an impulse follows the initial shock so closely that the two shocks are combined in a single seismic event—an earthquake with two foci, or a 'double earthquake'.

Prelude.—The forecasting of earthquakes by means

of prelude has nothing in common with other methods, but resembles rather the forecasting of the weather for the day by a glance at the sky in the morning. It depends on the recognition of premonitory signs; and also, to some extent, on the recognition of the earliest phases of the event itself.

When a fracture or other parting of the rock takes place, the jar which is communicated to surrounding portions of the crust is not a simple impulse, but a congeries of vibrations differing in amplitude and period, and in speed of transmission. At any point of the focus they begin together, but, traveling through the rock at different rates, they arrive at any distant point at different times; and the greater the distance the greater their separation. The strongest of the vibrations, or those said to constitute the principal shock, are not the first to arrive, but are preceded by vibrations which are much weaker, and are known as the preliminary tremors. At a point twenty miles from the origin the preliminary tremors are felt four or five seconds before the principal shock. There are also vibrations too minute to be felt, and not yet recorded by the most delicate seismographs, but of such frequency that they fall within the register of the ear and are perceived as sounds, and these usually begin to arrive before the preliminary tremors. The sounds and faint tremors are notes of warning, and to him who not only hears and feels but understands, they give command of precious seconds. People who live in earthquake countries and are familiar with these warnings acquire the habit of instantly taking precautionary measures.

Still earlier than the sounds and tremors with which the earthquake begins, are sometimes sounds, tremors, or minor shocks, and it is suspected that phenomena of this sort may betray growing seismic activity and thus constitute premonitory symptoms of the final rupture. Little is known of them in any exact way, because they occur at a time when attention is not directed to such matters; and nearly all records are made from memory after the occurrence of the earthquake. If they are veritable preludes, connected in a systematic way with the mechanics of the earthquake, they are probably analogous to the cracklings and crepitations observed in strained beams and strained blocks of rock before collapse occurs. With reference to the possibilities of forecasting, expectation centres especially on faint tremors such as are occasionally perceived a few minutes or a few hours before an earthquake shock. They are more frequently inferred from the peculiar behavior of animals; and after making much allowance for the influence of imagination on the memory of observers, there is still reason to think that various animals are affected by vibrations to which man is insensible, and that their reported uneasiness before earthquake shocks is real, and is occasioned by premonitory vibrations.

Summarizing briefly, many of the mallooseismic districts or areas of earthquake danger are known from records of past experience, and others are being recognized by physiographic characters. Within them are tracts of special instability because of the inco-

herence of the underlying formation, and these can be both characterized in general terms and locally mapped. The general relations of danger to place are so well understood that an early solution of their outstanding problems may be assumed. Of the relations of danger to time much less is known and there is less promise for the immediate future. The hypothesis of rhythmic recurrence has no sure support from observation, and is not in working order for either large or small areas. Its corollary of local immunity after local disaster is more alluring than safe. The allied hypothesis of alternation between parts of a district is being tested by a great example, but the verdict belongs to the future. The hypothesis of precipitation by accessory forces which are in large part periodic and foreknown, has a good status and is being developed on the statistical side. It promises to make the date of prediction more precise if ever the approximate time shall be achieved by other means. The hypothesis of an intelligible prelude has barely been broached and the means to test it are not yet in sight. In a word, the determination of danger districts and danger spots belongs to the past, the present, and the near future; the determination of times of danger belongs to the indefinite future.

It remains to draw the moral. In view of these facts as to forecasting, and of the further fact that we have in our land a district subject to strong earthquakes, there are duties to be recognized and policies to be advocated. It is the duty of investigators to develop the theory of local danger spots, to discover the foci of recurrent shocks, to develop the theory of earthquake-proof construction. It is the duty of engineers and architects so to adjust construction to the character of the ground that safety shall be secured. It should be the policy of communities in the earthquake district to recognize the danger and make provision against it.

The general fact of local danger spots, where the agitation during strong earthquakes is peculiarly violent, has long been familiar. It is known that they are commonly found in lowlands where the underlying formation is a deep deposit of alluvium or other unconsolidated material, and that such material, while it exaggerates the violence of great shocks, absorbs and quenches small ones. It is also known that the local phenomena are in some way connected with the transformation of earthquake waves in passing from elastic to inelastic material. But a mechanical theory of the phenomena is yet to be supplied. For economic, as well as scientific purposes, this is one of the important fields for investigation. In Japan, where earthquakes are much more frequent than in any portion of our own land, the subject has been studied and may still advantageously be studied, by the observation of natural shocks. In America the problem can be more readily studied by means of artificial earthquakes in the laboratory, continuing the line of experimentation begun by Rogers. When the underlying principles have become known, it will be comparatively easy for geologists, engineers, and architects to estimate the danger factor in places to be occupied by buildings.

MINERAL RESOURCES OF UTAH.

By ROBERT H. BRADFORD.

*In the production of the four important metals, lead, silver, gold, and copper, in the year 1907, Utah stood third in lead, third in silver, fourth in gold, and fourth in copper, among the States of the Union. Her copper output for 1908 will be far in advance of last year, with the promise of greater increase, due to the rapid development of mining at Bingham.

The Utah Copper Co. owns about 200 acres of ground in the heart of Bingham, besides 1000 acres near the mouth of Bingham canyon, and 2400 acres at Oatfield. The orebodies of the property in central Bingham consist of an altered silicious porphyry containing small grains of copper minerals uniformly disseminated through the mass, both in fracture seams and in the body of the rock. The ore averages about 2% copper, 0.15 oz. silver, and 0.015 oz. gold. The primary copper mineral is chalcopyrite, but as a result of secondary enrichment from above, practically all of the copper sulphide minerals are now present, the principal one being chalcocite. The developed area covers 72 acres of ground, and although the thickness of the orebody has not been fully determined, developments show an average depth of at least 310 ft. This area and depth of ore figures up to the equivalent of 1,000,000 tons of ore per acre. Besides these 72 acres now developed or partly developed, there are 88 additional acres of mineralized porphyry in the company's property. Open-cut work with steam-shovels is employed in the extraction of 80% of the tonnage of 6000 or 7000 tons of ore per day, the remaining 20% being taken out by the underground caving system. At the mine the company has in operation 15 steam locomotives, most of 100,000 lb. weight; 125 dump-cars of 6 cubic yards capacity, used for stripping overburden; two 40,000-lb. electric locomotives; three smaller electric locomotives, and the necessary cars for underground haulage; 6 steam-shovels; about 10 miles of standard-gauge railway laid with 65-lb. rails; a 300-hp. compressor plant; a completely equipped machine shop, capable of repairing the heavy locomotives and steam-shovels; besides commodious offices and quarters for employees. About 75% of the ore produced by the caving system is transported by the Copper Belt railroad to the Utah Copper Co.'s concentrating mill at Copperton, about three miles down the canyon. The mill has a capacity of about 900 tons per day. It was built originally for the purpose of developing the best process of concentration, but has been trebled in its capacity, and now is an important unit in the company's commercial mills. The mammoth concentrating mill is at Garfield, where the company has an abundant supply of water.

The ore is transported 15 miles northward by the Rio Grande Western Railroad Co. to the Garfield mill, on the shores of the Great Salt Lake, and there concentrated, putting 22 tons of crude ore into one ton of concentrate.

*Abstract of a paper read before the American Mining Congress at Pittsburg, December, 1908.

The concentrate from the monzonite ore forms a desirable smelting mixture. It may be smelted direct in the reverberatory furnace, or roasted preliminary to smelting.

Adjoining the Utah Copper mine on the south is the Boston Consolidated. The Porphyry mine of this company covers about 156 acres. A large portion is underlain by mineralized monzonite porphyry, similar to the Utah Copper ore, but running slightly lower in copper content. This is estimated by the company's engineers to average about 1.5%. The capping, or overburden, to be removed in order to mine the deposit by steam-shovel is about 100 ft. thick. The profitable ore over this area, as indicated by extensive equipment employed for stripping and disposal of the capping, and for the mining of ore

Map of Utah.

for the concentrating mill, has been in process of extraction for three years. This equipment is said to be ample for handling 15,000 tons of rock daily. The Boston Consolidated's concentrating mill is at Garfield, 15 miles in an air-line or 27 miles by railroad to the north. The mill will have a capacity for treating 3000 tons of porphyry ore per day. At present but eight units are in operation.

Besides the porphyry mine, this company operates an extensive sulphide mine covering 103 acres of the limestone belt. The ore carrying a high percentage of iron pyrite is not susceptible to concentration, but is sold to the smelter. The mine is fully equipped for the production of 750 to 1000 tons of ore per day by square-set stoping.

The Ohio Copper Co. adjoins the Utah Copper on the east, and the Boston Consolidated on the north, and covers an area of 120 acres. The ore is much shattered and broken. Copper is disseminated throughout the shattered rock, and especially along the cleavage planes in the form of a clean chalcocite,

associated with chalcopyrite and pyrite. Many crevices in the shattered quartzite have been filled by the metalliferous minerals, forming stringers and veinlets of rich copper sulphide.

From careful calculation of ore reserves there is estimated to be 13,500,000 tons of ore in the mine above the present transportation tunnel. The average copper content of the ore is 1.6 to 1.75% copper, with some 10c. in gold and 3c. in silver per ton. The concentration of this ore is a simple matter, as the copper minerals are not as finely disseminated through the rock as they are in the porphyry of the neighboring properties. The absence of any clay or talcose decomposition-products of the rock make this quartzite an exceedingly favorable ore for concentrating. The mill tests have given an extraction of 75 to 80%. A concentrating plant of 2400 tons daily capacity is now built at Lark, three miles to the east, for treating this quartzite.

The Highland Boy mine of the Utah Consolidated Co. was one of the early producers of the high-grade sulphide ores of the district. The ores of this company were smelted for a number of years at Murray, Salt Lake county. The ore averaged high in copper, and the output of the smelter in copper bullion was large in consideration of the ore-tonnage treated. The high-grade ore, and the favorable conditions for mining and smelting, were indicated by the dividends disbursed. These amounted to more than one million dollars per year. Since the closing of the Murray plant by the injunction obtained by the farmers of the valley, the ore has been treated at the American Smelting & Refining Co.'s plant at Garfield.

One of the large producers of the sulphide ores of Bingham is the Yampa mine. The ore is practically self-fluxing, but needs a small amount of limestone. The mine is delivering 700 to 800 tons of ore per day, which is transported about 1½ miles to the Yampa smelter, in Bingham canyon, the cost of transportation being seven cents per ton. The smelter treats the total tonnage of the mine, besides about 200 tons of custom ore daily.

The extensive properties in Bingham canyon owned by the United States Mining Co. are producing a large tonnage, that is all smelted at the United States smelter at Bingham Junction, in Salt Lake county. The ores are transported by an aerial tramway to the Rio Grande Western railroad at the Bingham terminus, and thence hauled to the smelter, 12 miles away.

Tintic has achieved and still holds the enviable distinction of having more dividend-paying mines than any other district in Utah. Eighteen of her mines are credited with having paid dividends of \$17,000,000. The Centennial Eureka, one of the richest mines belonging to the United States Smelting & Refining Co., has of late years been the heaviest shipper. The Bullion Beck, one of the oldest producers in the district, has recently gone into the hands of the United States Co., and will be exploited more actively in the future. The Eureka Hill leasers have been active during recent years, and have produced large quantities of good ore. The Mammoth

and Grand Central seem to show no limit to the depth at which they obtain profitable ore. East Tintic, upon Godiva mountain, has shown great activity during the last two years. The May Day and Uncle Sam have both benefited by the union they effected during 1907. During 1908 there have been paid out, by these companies, nearly \$150,000 in dividends. The Knight properties, Crown Point and Iron Blossom, controlled by Jesse Knight, of Provo, Utah, have made a phenomenal record since their exploitations commenced three years ago. The Colorado has taken the lead by producing nearly a million dollars worth of ore in 1907 and paying an aggregate of nearly \$800,000 in dividends during that year. The output averages from \$75 to \$100 per ton in lead, silver, and gold. The Beck Tunnel has been a close follower, with ore values averaging somewhat less, but with a total dividend-record near the \$700,000 mark, but distributed over a considerable period of time. As evidenced by the miniature dumps at the shaft of these two mines there has been little dead work. Practically everything taken out has been shipping ore. The lime formation of East Tintic has responded so abundantly to the efforts of the miners that now a circle of dividend paying mines is found upon Godiva mountain, including the above mentioned properties, the Yankee Consolidated, the Gemini, the Sioux Consolidated, and others. Tintic suffered considerably by the closing down of the Salt Lake county smelters and a consequent cutting off of the market for ores. At present, since an amicable agreement between the farmers and the lead smelters has been entered into, relief has been furnished. Jesse Knight and his associates have organized the Tintic Smelting Co. and have started up during the present year a lead smelter of 350 tons capacity. This plant is in Tintic, and furnishes a ready outlet for the products of many nearby mines. Owing to the recent unfavorable metal market, this lead and silver camp for the first half of the present year marketed practically no ore. But during this period much development work was done, which opened up orebodies that made it possible for some of the largest companies to ship even better ore and a larger tonnage than ever as soon as metal prices improved.

The persistence of rich ore in the Park City mines as depth increases makes it important to provide proper drainage. The Ontario drain adit, 3 miles long, was constructed for this purpose. The caving of this adit a few years ago caused the lower levels of some of the large mines to become flooded. By intelligent and untiring effort this has, during the year, been re-opened. It has also been extended back under the Daly and Daly West mines. It will cut the Daly West shaft at the 2100-ft. level, giving this mine 600 ft. additional vertical depth. The Daly West main shaft is being deepened to meet the adit, and is now near the 1700-ft. level. The Silver King mine has made important discoveries of high-grade ore during recent development that puts it in possibly better condition than ever before. This mine, the Daly Judge, and the Daly West are shipping a fair tonnage. The new developments in the

Park City district have been made recently in Thaynes canyon, toward Brighton. Prospects showing great activity there are the Copper Apex, Keystone, Uintah Treasure Hill, New York, Wabash, and Silver King Consolidated.

Utah's famous gold producer, the Consolidated Mercur Gold Mines Co., is the leading gold-producer in the State. During the past 15 years many millions in gold have been taken from the properties of this company. The total dividends to date paid by the present company, and by the old De Lamar and Mercur companies, run up to the handsome sum of \$3,385,312. This amount shows the success that has attended the persistent efforts of John Dern and his associates. The Boston Sunshine Gold Mining Co. has re-constructed the mill of the old Sunshine mine of Mercur, and is adding new equipment preparatory to cyaniding the argillaceous, refractory ores of the once famous Sunshine mine. The mill will have a capacity of 200 tons per day, and will be put into commission during the month of January. Other important mining districts of the State are: Alta, Big Cottonwood, American Fork, Deep Creek, Beaver County, Kimberly, Park Valley, and Gold Springs.

The State also yields many valuable non-metallic minerals. The waters of the Great Salt Lake are furnishing yearly about 40,000 tons of salt, supplying most of the States west of the Missouri river. The saturated brine of this great body of salt water contains an almost unlimited supply of the mineral so essential to human life. There has recently been explored an immense salt bed in the Great American desert, about 110 miles west of Salt Lake City, 15 miles east of the Utah-Nevada State line. The Western Pacific railroad has built directly through these beds. This salt covers an area of 60 square miles. The deposit varies in depth from 6 in. to 7 ft. or more. It is almost perfectly white, and absolutely free from dirt, rubbish, or growth of any kind. The United States Congress, by the provisions of the Enabling Act for Utah, gave to the University of Utah all the saline lands of the State. Notwithstanding this fact, prospectors have staked their claims over the deposit, and are contesting the University's rights in the courts. The Supreme Court of Utah during the past week gave its decision in favor of the State University, but the case may not be finally disposed of until the United States Supreme Court renders its decision.

There are four extensive coalfields being operated at present in the State of Utah. These include the Book Cliffs, the Weber River, the San Pete, and the Iron County fields.

The asphalt deposits of eastern Utah are world-famous for their extent and purity. The principal minerals consist of uintahite, wurtzillite, elaterite, ozocerite, and maltha, besides a variety of asphaltic limestones, sandstones, and shales. Uintahite, or the gilsonite of commerce, is the most important. It occurs in true veins cutting the sedimentary rocks of the region. In extent and purity these deposits far surpass any others now known.

Other mineral deposits of great value in the State include fire-clay, gypsum, phosphate, ornamental

stones, uranium, vanadium, and radium minerals that up to date have been but partly developed, and there are notable beds of iron ore. The iron deposit in Iron county, in southern Utah, occurs as a mountain of ore, 15 miles long and 3 miles wide. Hundreds of acres of this mountain of ore will require no stripping, and in greater part it will respond readily to the steam-shovel. Analyses of numerous samples by the United States Geological Survey show from 59 to 65% metallic iron.

The smelters now available in Utah, with their capacities, are as follows:

	Tons Daily.
Murray plant, American Smelting & Refining Co., lead	1,500
Garfield plant, American Smelting & Refining Co., copper	3,000
U. S. Smelting Co., Bingham Junction, copper.	1,500
U. S. Smelting Co., Bingham Junction, lead...	1,000
Yampa smelter, Bingham canyon, copper.....	1,000
Utah Smelting Co., Ogden, copper.....	250
Tintic Smelting Co., Tintic, lead.....	350
Tintic Smelting Co., Tintic, copper.....	150
Total	8,750

FINK COPPER SMELTING PROCESS.

At 10 o'clock Saturday night, January 16, the first pouring of blister copper ever made in a single process furnace was accomplished at the Edward Fink plant, at Garfield, Utah, near the Boston Consolidated mill. With 15 men on a shift, and with the utilization of 25 hp. and a couple of tons of fuel, the Fink smelter has demonstrated its ability to convert Boston Consolidated concentrate into copper matte at the rate of 100 tons per day.

In the Fink plant 95 to 98% copper matte is produced at the one operation. Nothing like it was ever accomplished, and some of the best metallurgists and expert smeltermen in the business have doubted whether Edward Fink would accomplish it in a commercial way. Samuel Newhouse, daring and progressive in all that pertains to mining, was approached by Mr. Fink, and heard from him the details of the scheme. It appealed to him as having merit, so he made an agreement with Mr. Fink to bring the process to the attention of the world. He gave the inventor carte blanche in having an experimental furnace of commercial size built, one that would treat 100 tons per day.

At the trial run, in less than one hour after the ore was fed, the molten matte was allowed to run into the pots. One bar was run out into a flat mold, and the sample, weighing possibly 150 pounds, was taken to Salt Lake City.

The process consists in reducing copper concentrate directly in a revolving barrel-shaped 'converter', so-called. Gas and pre-heated air are blown in at one end, and the direction of the flame may be reversed at will, as with furnaces using regenerative chambers. Through the ports at each end of the barrel inclined tuyeres extend down into the charge. As soon as the charge has become molten the tuyeres are lowered and desulphurization and oxidation of iron proceed until a highly enriched matte is produced.

PROTECTION OF INVESTORS.

The second meeting of the Pacific Coast division of the Mining and Metallurgical Society of America was held in San Francisco on December 19, the discussion of the previous meeting being continued, as follows:

S. B. Christy.—At our last meeting Mr. Bradley opened the discussion, insisting on the idea that reports issued by mining companies should state the amount of developed ore, the amount of ore that was probable, and the amount of ore that was possible, both in tonnage and in average value. The general consensus of opinion was that the nature of the evidence on which a judgment was based should also be given. The question is: "What are the essential items of information which should be contained in mine reports for the full protection of investors?" We have agreed that the report of the management should give a clear and definite statement of the amount of ore exposed and ready for stoping, and that it should be indicated on what basis the estimate was made. It is evident that other items are required.

F. W. Bradley.—I would suggest that in addition to the physical value of the property, there should be a clear statement as to the financial conditions. This is something that is not often clearly set forth in a report. We touched on just one item at our last meeting, namely, the question of ore reserves, which in my opinion is more important than anything else; but there are other items that should be discussed, although I do not know that we have yet finished the question of physical valuation.

W. H. Shockley.—Some mines never have any ore reserves. It seems to me that Professor Munroe has summed the thing up so well that there is not much more to be said. The question is how much money you can make out of the ore.

M. L. Requa.—I think Professor Munroe has laid too much stress on the time that a mine is likely to last. Of course, it is hopeless to attempt to safeguard the public in the preliminary stage of mining development. We all know that the unexpected often happens and we may run into bonanza or into borrasca; but after that there comes a stage when you can give some definite figures on vital points; and while it is desirable to have the report go into details as to the cost and how those costs were arrived at, yet, following that, for the benefit of the layman, I think that a concise statement, based upon those detailed figures, is much more interesting to the average investor than the mere recital of the various items that go to make up the cost.

T. A. Rickard.—Munroe goes into that by saying that he wants it determined by some competent man.

M. L. Requa.—That is a very broad question. It can be boiled down by taking the figures in detail and compiling from that the ore actually developed and ready for stoping; this should be segregated in a paragraph by itself, giving the tonnage, the assay-value, the extraction, and finally the net value of the ore applicable to dividends—that is what the shareholder wants to know.

W. H. Shockley.—And how long those dividends will continue.

M. L. Requa.—That depends entirely upon the size of the plant; it should be stated in the report what tonnage you can work annually. Following that, in a separate paragraph, I would include a statement of partly developed ore, carrying out exactly the same set of figures as to the net value to be won, available for dividends, and reducing that right down to dollars per share of capital stock. Then, a third item giving the probable extension of the orebodies as yet undeveloped on the levels above the bottom, with the same tabulation. And finally a statement as to the bottom of the mine. The personality of the mine manager becomes a large factor, as to what he can consistently say regarding the probable future life of the mine, the possible depth to which the pay-ore will continue—this, while it cannot be expressed in actual dollars, has a direct bearing upon the ultimate value of the stock. I noticed in reading Professor Munroe's remarks that he laid considerable stress upon the life of the mine. Some mines, notably in the State of Nevada, are possibly short-lived; yet they produce an enormous amount of money applicable to dividends, and a statement regarding the probable length of the life of the mine would be misleading unless coupled with some information as to the probable amount of money to be derived during that period. There are certain statements that you can make positively, and others that you cannot. It might be possible to compel mining companies under a State law to render reports upon certain fixed lines that would largely embrace all the necessary information.

W. H. Shockley.—I do not see why it could not be done.

Charles Butters.—The element of chance makes it impossible to establish any fixed rule; you may tell a man definitely what he will receive upon his investment, but that element of doubt remains, particularly in Nevada, for tomorrow or the next day you may run into a bonanza that will smash all your calculations.

T. A. Rickard.—The average investor would like to know whether the stock is going up. He does not care about the mine.

S. B. Christy.—I think that is true everywhere.

Charles Butters.—That is not true in England as regards South African stocks.

S. B. Christy.—The English take a different view about matters of that sort. It is partly a sentimental view. Many of my friends who have been in Rhodesia have told me that the English are willing to spend money freely without any hope of return simply for the reason that they want to develop the country. They have the instinct for land-grabbing, and they feel it their duty to develop the country so that future generations may benefit by it—sow the seeds of Empire—that idea is strongly developed.

W. H. Shockley.—I have attended a good many meetings of mining companies in London, but I never heard anything about the Empire; the talk was all of profit and loss. The essential things to know are: the number of shares of stock, how much will be paid

in dividends, the length of time it will take to work out the mine, and the value of the improvements, buildings, machinery, and material on hand when the mine is exhausted. From these data the investor could value the shares of the company. The dividend-value of the ore is always an uncertain quantity; there is usually a certain amount of ore that is developed, and as to the amount of which two engineers would agree; besides this there are apt to be possibilities for ore which would be differently estimated by equally able engineers. These possibilities should be reduced to definite figures; so much in dividends per share. Thus one could do a good deal of theorizing as to the possibilities in depth or laterally. But eventually, in almost all the precious-metal mines, you have got to do a good deal of guesswork. It is not like a bank statement. Take men who are perfectly expert in the business, who have had the same experience, and yet they will arrive at widely different conclusions. It is largely a matter of judgment. You must do as they do in New Jersey when they weigh sheep. They put the sheep on the end of a rail and balance the rail on a fence and put a sack of stones on the other end, adding or taking away from the stones, and when they get the rail balanced, they estimate the weight of the stones. And there is a good deal of that same thing that has to be done in mining. Again, mining is looked on by almost everybody as a means of gambling, like race-horses or a faro-table. A man buys shares on the theory that they are going up, and he is going to sell them when they advance. Of real investment in precious metal mines I have not seen very much. A great many people have been misled of course, especially Eastern people, by statements that have been issued by promoting concerns. Take the Sullivan Trust Company at Goldfield. The amount of money they got out of the investing public was enormous. At one time I understand there was \$100,000 per day paid in to them; and the statements as to the value of their mines were absolutely false in most cases. There should be some means of having such statements corrected as soon as they are made, by some competent authority. I do not know how you are going to get at it exactly—government experts, perhaps.

F. W. Bradley.—It is often difficult to learn from reports whether a company has money on hand or is in debt; the financial conditions should be clearly set forth, as Professor Christy suggested. As regards costs, I think Mr. Comstock handled that in good shape. Rather than have a mass of details, the ordinary shareholder would prefer to know the lump cost of principal items and a comparison by years in order to determine whether the costs are increasing or diminishing.

C. C. Derby.—Would you make any segregation of costs?

F. W. Bradley.—That also was covered in Mr. Comstock's paper. It is well enough to have the complete details in arriving at lump costs, but in presenting them to the ordinary shareholder, he should not be bothered with too much detail. It is more to the point for him to have the totals of the principal

items, so that he may know by comparison whether those items, per unit or per ton, are increasing or decreasing.

T. A. Rickard.—Our guest, Mr. Erb, is the secretary of the Mine Operators' Association of Goldfield, I believe, and it occurs to me that being a man who is closely in touch with the practice in that district, he may be able to give us some interesting information.

William Erb.—Anything I may say will be purely an offhand statement. When the cold calculating business-man is considering a venture, he looks at the men at the head of it. A mine may be worth as much today as a year hence; but today it is manned and managed by a man not competent; you have nothing to do with it; a year hence it has passed into the hands of a man who has your complete confidence, and by reason of that confidence the shares advance.

T. A. Rickard.—All the difference between Sullivan and Mackenzie?

William Erb.—Exactly; that is the story in a nutshell. In each instance you have to differentiate between a mine and a prospect. When you have got a mine it is not at all difficult to get people who know, to come into it on the point of dividend returns. But when you have a prospect, or something between a prospect and a mine, you will always have people who want to gamble, and they will not gamble on what the mine is; they are going to gamble on the personality of the man that presents it to them. The Sullivan Trust Co. affair was one of the cleverest advertising schemes in the world, putting out alluring prospects of returns of ten thousand to one. Every day in my mail came in letters, "You in your capacity are undoubtedly acquainted with such and such a mine." I never heard of the mine, and never heard of the people connected with it. These letters were written by my own friends in San Francisco, reputable business-men. They would write and ask: "Have you heard of this mine?" I had not. But if I went to those men and said: "I have 8 ft. of \$200 ore, and if you put your money into the mine, you will get 40 cents per annum for every dollar you invest for 10 years to come," they would be incredulous. Yet they will invest in a prospect that is put to them in an alluring sort of way.

T. A. Rickard.—Could you suggest some way of protecting these innocent people?

William Erb.—No, I cannot. The story dates back to the time when a man had a number of sons and the name of one of them was Joseph. He was a better man than his brothers, and because he could get on the better side of his father, they lowered him into a well. But he finally got into a good country, and there proved himself to be the better man after all.

S. B. Christy. It seems to me a hopeless task to try to protect a certain class of people; there always will be one class preying on another. We are interested in the general welfare of the whole industry. I think a certain amount of foolishness is inevitable. I believe that certain kinds of mines would not be developed were it not for this speculative instinct.

If it were all a cold-blooded proposition there are lots of mines that would never be opened at all. But we all feel that there should be some distinction in reports between what is reasonably certain and what is chance. Of course if people go into a proposition that is distinctly a chance, they should not squeal. And it is fortunate that some men are willing to lose, for it results in the development of legitimate mines.

C. W. Merrill.—Is not the question under discussion the protection of the investor, rather than the protection of the speculator? It seems to me that the developed property has to do with the investor.

S. B. Christy.—There is a good deal of money invested in Nevada that comes from speculation, and some of it is used to good advantage.

C. W. Merrill.—Of course, I am more of a metallurgist than a miner, but it seems to me that in connection with a well developed property it ought to be possible to establish a form for reports such as Mr. Bradley and Mr. Requa have suggested, and it need not be particularly complicated; but in the valuation of the mine, the dividends that can be produced from the ore in reserve, the possibility of reduction in operating cost should be stated fully and also the possibility of increased extraction—these matters should appear in each report as the matters suggest themselves and as the development continues. It seems to me that when that is done we shall have covered the matter fairly well. Let it be done in a concise and definite way. The question of possible ore reserves is interesting, but it is problematical. If we state what ore is in reserve and what it will cost to get the values out of it, what the chances are for improvement and reduction in cost and increase in yield—that is what the mining investor ought to be told. Possibly a model of such a report would be a good thing, and if it were possible to make it compulsory, so much the better. But I do not think, as Mr. Comstock said, it is going to be possible to do it by State regulation.

Albert Burch.—I do not believe that it is possible to make it compulsory. You can provide a penalty for publishing a falsehood in connection with a mine, but you cannot pass a law compelling the issuing of reports which will really be of any value, if the officers care to evade the law in the matter of making such reports. Take, for instance, the weekly reports that come down from the superintendents on the Comstock. They have to state certain facts, and those reports state the truth; but they state the truth in such a way as to conceal the information that they are really intended to give. For example, a drift is reported to have been run so many feet in a certain week; the face of the drift is in porphyry. The controllers of the mine have in mind a depression of the stock with a view to buying it and later selling it at an advance. They are driving that drift right alongside of a body of ore and know it, for they drive drill-holes into the ore and know it is there. Later on they can publish an account of a great strike; then the public will learn what the management has known all along. You cannot compel a man to make a report stating the facts unless the people who know it want it published. But you can punish for false

reports, and it seems to me that it is toward that point that State regulation should be directed, and let the really affirmative part of the reform come in the shape of setting good examples, voluntarily.

Whitman Symmes.—I would like to make one suggestion, namely, that most mining companies should make fuller statements as to how their money has been expended. Scattered over Nevada, and elsewhere, are many companies that have taken the public's money, and have appropriated only a small portion of it to the development of the mine. It seems to me that if a form were made out upon which these companies had to state how their moneys were expended, a great many of them would not dare to go on in the way they have been traveling. For instance, if their expenses were segregated into power and pumping, shaft sinking, driving of drifts, extraction and reduction of ore, new plant, salaries, and office expense, it would stop a great deal of wastefulness. It is not enough for us to recommend that companies report the amount of ore developed and partly developed; the expenditures at the mine should be segregated so as to properly explain what is being done with the money. I believe that the first step taken by any of us here, when looking into the management of a mining company, should be to segregate the expenditures so as to ascertain the different items that I have mentioned. We would try to find out what the men in charge were doing with the money they were expending, and then we would pass judgment quickly as to whether the mine were being honestly run or not. In regard to writing a report that will be intelligible to the general public, I must say that I do not think such a thing is possible, because the general public is not versed in mining. When a man applies to the United States Government for a patent upon an invention, there are certain specifications describing that invention which the applicant has to place on file. The Government does not require that the specifications shall be so worded as to be intelligible to the ordinary person, but that it shall be so worded as to be intelligible to 'one skilled in the art'. It seems to me that a mining report should be framed in a similar manner, so that it will be intelligible to one skilled in the art of mining. If that be done, it will then be easy for an investor to take the report to one versed in mining, and to find out from the latter the pros and cons that are disclosed by the report. If he does not do so, the fault is then all his own.

(To be Continued.)

Lime slaked with hot water, according to Leo D. Bishop, causes slime to settle with nearly twice the rapidity of lime slaked with cold water. Mr. Bishop also calls attention to the great difference in effectiveness of different limes as coagulators for slime. The composition, as well as the perfection of burning, are important. In short, the more CaO the lime contains, the more it is worth.

The Treadwell mines, on Douglas island, Alaska, showed a notable increase in gold production, the output for the year 1908 having been \$3,081,454, against \$2,515,098 in 1907.

PROGRESS IN ALASKA.

By ALFRED H. BROOKS.

The value of the mineral production in Alaska for 1908 is estimated at \$19,600,000, as compared with \$20,871,771 for 1907. This decrease is to be charged to the gold placers and copper mines, as most of the other mining industries show an increase in value of output. The value of the total mineral production from 1880, when mining first began, to the close of 1908 is, in round numbers, \$148,000,000. Of this amount the gold mines have produced about \$142,-000,000, the silver output is valued at \$1,150,000, and the copper at \$4,100,000. The balance represents the value of the marble, gypsum, tin, and coal product.

Measured either in terms of production or of work accomplished, 1908 was not a prosperous year for the mining industry of Alaska as a whole. The causes that brought about this retardation were in part those affecting the mining industry everywhere; in part they were due to conditions peculiar to the North.

Mining, like many other industries, was seriously affected by the business stagnation that followed the financial panic, and the concomitant fall in the price of copper led both to a decrease in the output of that metal and to a diminution of activity in the preparations for future extraction.

Gold placer mining experienced a decided setback because of the drought that prevailed throughout the summer months in nearly all the important districts. The lack of water so curtailed the output of the Yukon and Seward Peninsula districts that the value of the total output of placer gold from these sources was probably nearly a million and a half less than in 1907. This decrease of the placer-gold production for Alaska as a whole is, however, but temporary, for the maximum annual output of the gold-bearing gravels has not yet been reached.

In spite of the business depression, the production of the auriferous lode mines of Alaska was about 27% greater than in 1907.

Among the conditions that are retarding the advancement of the mineral industry are the inadequacy of the public-land laws under which placer ground is acquired and held, and the impossibility of obtaining title to coal lands.

Improved transportation facilities are among the most urgent needs of the region. Much progress was made during 1908 in the construction of wagon-roads and trails, but these can only supplement and not supplant railways. The inadequacy of river transportation in seasons of low water was emphasized by the conditions on the Yukon last summer.

The advancement of several railways, such as those to the Matanuska coalfields and to the inland copper districts, from both Valdez and Katalla, which had been actively pushed during 1907, was greatly retarded by the financial conditions. In gratifying contrast to the slow headway made by these enterprises was the rapid progress of a railway being built up Copper river from Cordova. This line was completed to Childs glacier in September. In connection with this road steamers are to be run from Abercrom-

bie rapids, so that during the coming year it will be possible to avoid the long overland journey from the coast to reach the Chitina copper belt. As the railways in Alaska are of much public interest at present, the following table of mileage has been compiled from the best data available:

MILEAGE AND TERMINALS OF ALASKA RAILWAYS, DECEMBER 4, 1908.

Seward Peninsula:	Miles.
Seward Peninsula Ry., Nome to Shelton.....	80
Paystreak Branch S. P. Ry.	6.5
Council City & Solomon River, Council to Penelope Creek	32.5
Wild Goose Ry., Council to Ophir Creek.....	5
Fairbanks:	
Tanana Valley R. R., Fairbanks and Chena to Chatanika	46
Kenai Peninsula:	
Alaska Central R. R., Seward to near head of Turnagain Arm	53
Copper River:	
Copper River R. R., Cordova to Childs Glacier....	58
White Pass:	
White Pass & Yukon R. R., Skagway to White Pass (Terminal at White Horse, Yukon Territory.)	20.4
Yakutat Bay:	
Yakutat Southern Ry., Yakutat to Situk River...	9
Portions of the Council City & Solomon River and of the Alaska Central are out of repair and not in use.	

The following table indicates the source of the precious metals. The value of copper is estimated at 13.2 cents per pound.

SOURCE OF GOLD, SILVER, AND COPPER IN ALASKA IN 1908.

	Gold.	Silver.	Copper.
Silicious ore	\$ 3,525,000	\$20,000
Copper ore	75,000	25,000	\$634,000
Placers	15,000,000	35,000
	\$18,600,000	\$80,000	\$634,000

Twelve gold and silver lode mines were on a productive basis in 1908, as compared with 13 in 1907. The number of placer mines operated cannot be stated, but there were not so many as in 1907. Nine copper mines made some shipments of ore, as compared with 13 in 1907.

The tonnage of all the lode mines in Alaska for 1908 is estimated to have been between 1,650,000 and 1,700,000 short tons, as compared with 1,308,506 short tons for 1907. Of this amount, about 1,550,000 to 1,600,000 short tons represent the silicious gold ore and the balance the copper ore. The valuable contents of the ores mined will not be known definitely until accurate statistics are available, but they probably do not differ materially from those of last year, which showed an average gold content for the silicious ores of \$2.30 per ton including the Treadwell, and \$3.41 per ton excluding the Treadwell.

The copper ores in 1907 yielded an average of \$1.30 per ton for gold and silver, and 3.18% copper. It is probable that the copper percentage for 1908 has been slightly increased, as with the low price of copper only high-grade ores could be profitably mined and shipped. It is estimated that the copper production of Alaska in 1908 was about 4,800,000 lb., as compared with 6,308,786 in 1907. Of the 1908 production, somewhat over 1,000,000 lb. should be credited to Prince William Sound and the rest to the

Kasaan Peninsula and Copper Mountain districts of Prince of Wales Island. Considering the low price of copper during 1908, this output is exceedingly creditable, and indicates that the coastal mines are in a position to produce this metal at a low cost.

The statistical data for the placer mines are yet incomplete, but it appears that the output has a total value for 1908 of somewhat over \$15,000,000, as compared with \$16,491,000 in 1907. This decrease is chargeable to the adverse conditions of mining because of the scant water supply in the Yukon and Seward Peninsula districts. Had there not been this shortage of water, the placer-gold output would have far exceeded that of 1907.

Though the decreased output was due to the lack of water, yet it can not be denied that the approaching exhaustion of some of the bonanzas, such as the third beach line at Nome and parts of the developed channels at Fairbanks, would have much curtailed production had not other similar rich deposits been found. Placer mining in Alaska up to the present time has been largely a matter of taking the cream of some of the richest deposits, and even this often at an almost prohibitive cost. It has been chiefly in the hands of the pioneer, who often may have neither the patience, the capital, nor the experience to exploit anything but the bonanzas. Throughout Alaska there are few well-managed enterprises endeavoring to recover the gold from the larger bodies of low-grade alluvium. Until a change is brought about in the mining conditions it must be expected that there will be marked fluctuations in the gravel-mining industry—an advance with the discovery of new rich deposits, a retrogression as quickly as these are mined out. With the advent of capital and skilled engineers, methods will be improved, the many large bodies of gravel having smaller gold contents will be exploited, and the industry will be placed on a more stable basis. The whole future of the industry depends on this economic revolution, and the quicker the change is brought about the less likelihood is there of a long period of stagnation after the richest deposits have become exhausted. This conclusion does not imply the improbability of other discoveries of the same grade as those that have made the country famous; it only emphasizes the fact that permanent industrial advance can not be founded on bonanza mining.

The summer of 1908 brought convincing proof that the water supply in most of the placer camps is inadequate for the needs of the placer miner. With a precipitation of 10 to 16 inches in the Yukon basin and 15 to 30 in. in Seward Peninsula, the climate must be considered semi-arid. Moreover, the frozen condition of the subsoil prevents any ground storage, and the low stream-gradients are unfavorable to the utilization of the water-supply. All these factors go to show the inadequacy of the surface waters to the needs of the placer miner—an inadequacy that is emphasized by such dry seasons as those of 1907 and 1908. Unfortunately the operators, slow to recognize this, have been only too ready to regard some of the years of heavy precipitation as normal, and many of those of low or moderate precipitation as ab-

normal. Many hundreds of miles of ditches have been constructed, or partly constructed, and many expensive plants installed for which the normal water-supply was absolutely inadequate. The problem of mining the gravels with an inadequate water-supply presents many difficulties, but it will be solved. It is probable that power will be obtained for pumping and other purposes by utilizing water-power or the extensive deposits of lignitic coal found near some of the placers.

The introduction of dredges, both in the Yukon and Seward placers, is a promising feature of recent advancement, although here too the lack of experienced engineers or capital has worked havoc with many enterprises. Probably nearly a hundred dredges have been built in this northern region, and most of them have been utter failures, but there is, nevertheless, no question that the dredge is to play an important part in Alaskan mining operations in the future. In 1908, including those in the Klondike, nearly a score of dredges were successfully operated. The statement that there are large areas of dredging ground should not, however, be interpreted to mean, as it appears often to have been in the past, that any auriferous gravels which could not be mined by other means furnished suitable ground for dredge-mining. Frozen ground is a serious obstacle to dredging operations, but experiments in thawing by both natural and artificial means, now being made, will solve this difficult engineering problem.

The results of these operations and investigations are as yet far from conclusive. It appears, however, that where the ground is unfrozen, dredging can be done at a rate of from 12 to 40 cents per cubic yard. Thawing by artificial means can probably be done at a cost varying from 12 to 25c., while thawing by exposure to the air and with the aid of water is much cheaper. These figures apply to ground probably not exceeding 25 ft. deep. The maximum here presented (65 cents per yard) does not appear excessive to those familiar with the high cost of mining in most of the placer districts. Little of the gravel now handled at Fairbanks, where most of the mining is done at a depth of from 30 to 150 ft., carries less than \$4 to \$5 per yard in gold. Where ground is shallower, probably gold to the value of \$3 to \$4 per cubic yard can be profitably recovered.

One half of the natural gas now coming out of the earth, about 1,000,000,000 cu. ft. per day, or more than enough to light all the cities of the United States having more than 100,000 population, is wasted by being allowed to escape into the atmosphere. This entire waste can be prevented by adequate State legislation, similar to that now enforced in Indiana and one or two other States.

Diamonds are being produced in considerable quantity from the recently discovered Luderitzbuch field, in German Southwest Africa. The Weiss de Mellion Co. is producing from 12,000 to 15,000 carats per month. The bulk of the diamantiferous area has been acquired by three companies. The diamonds range mainly from a sixth to a third of a carat.

SINTERING AT CERRO DE PASCO.

A special commission to report on the operations at Cerro de Pasco was appointed in 1907, and has continued its functions into the present year. Bulletin No. 61 is the fruit of its labors, containing a large amount of interesting data, from which is abstracted the following account of a system of ore-agglomeration, or sintering, which will be of interest in comparison with the Huntington-Heberlein, Dwight-Lloyd, and other sintering devices now offered as a substitute for briquetting in the preparation of fine material for blast-furnace smelting.

The Cerro de Pasco Mining Co. has recently installed 14 sintering furnaces at its smelting works at Tinyahuarco. In these ovens are agglomerated the fine ore passing the grizzlies, and the flue-dust from the condensing chambers at the smelter. A series of 10 hoppers, of which 5 are for fine ore and 5 for flue-dust, discharge upon an endless belt-conveyor 112 feet long by 22 in. wide. The mixture as it falls upon the belt is sprayed with water until it contains 10% moisture. The material thus dampened passes to a screw-conveyor, which serves both to mix the fine and the flue-dust, and automatically to feed the mixture to an elevator. The elevator discharges into a large hopper, whence the material is transported in cars to funnels which are placed above each oven. Alongside of these are other funnels for feeding limestone. The operation of the belt-conveyor and the elevator is effected by means of an electric motor rated at 50 kw., 400 volt, 60 cycle, 3 phase, 66.5 amp., running 850 rev. per minute.

The accompanying sketch will illustrate the construction of the sintering furnace or oven. It is composed essentially of two parts: an upper movable portion of iron, which actually constitutes the oven where the sintering is done; and a lower portion of brick-work. The upper part consists of a grating so suspended by a central axial bar that it may be rotated for convenience in discharging its burden. This grating has a superficial area of 124 sq. ft., and consists of three groups of bars, of quadrangular section, narrower above than below. The central portion also has somewhat larger bars than those on the sides. This grating is covered by a movable hood 3 ft. high. Into the upper part of the pyramidal hood are led two tubes for an air-blast, which is delivered at a pressure of 5 oz. To effect a seal against the escape of air, there is an asbestos packing between the bottom of the hood and the brick wall on which it rests.

The lower part of the furnace, corresponding in position and design to an ash-pit, serves as a bin for the agglomerated material. It is square, with a sloping bottom, as shown in the cut, so arranged as to dump into cars on a track below.

The operation is conducted as follows: upon the grating enough crushed limestone is drawn completely to fill the spaces between the bars, and thus form a bed, upon which is placed the mixture to be

sintered. This is lightly raked over so as to be spread evenly. Upon this wood chips are thrown; these are kindled by means of hot coals drawn from a perambulator-hearth on wheels. The hood is then lowered and the air-blast turned on. Normally the operation lasts one hour. At times the bed lacks porosity, which causes the blast-pressure to channel the bed and fail to effect the roast. When agglomerated the hood is raised, and the grating revolved on its axis, dumping the charge into the bin below.

At the present time only 4 ovens are in service, which treat 30 tons each in 24 hours. The desulphurization effected is from 5 to 1, the average sulphur content of the original charge being 20%. The copper-content of the charge averages from 10 to 12%

Sintering Furnace or Oven.

in the fine ore and 14% in the flue-dust. The system cannot be said to be highly economical. The labor-costs are high, two men being employed for each furnace, on 8-hr. shifts. Losses and inefficient agglomeration result from failure to add just the correct quantity of water. Furthermore, the method of igniting the charge is poor and tedious, and adds extraneous matter to the charge. Efforts were made to ignite with petroleum, but this only served to augment the costs.

Excavation on the Panama Canal is proceeding rapidly. Since the Government took up the work, from May 4, 1904, to the close of 1908, 59,773,179 cu. yd. has been excavated, of which 37,016,693 cu. yd. was taken out during 1908. By the French companies 81,548,000 cu. yd. was excavated. From the appropriations for canal construction, the expenditures from May 14, 1904, to October 1, 1908, were \$83,275,000. Of this amount \$51,512,000 was expended by the Department of Construction and Engineering.

*Translated for the MINING AND SCIENTIFIC PRESS from a Report to the Peruvian Minister of Fomento.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

ACTION TO RECOVER MINES—INJUNCTION.

In an action in ejectment to recover certain mining grounds the plaintiffs were entitled, under a statute giving an injunction where another is doing or threatening to do some act in violation of the plaintiff's rights and tending to render any judgment recovered ineffectual, to an injunction ancillary to the main action restraining the defendants from operating a mine on the ground in controversy, pending the action, on a showing that such ground was chiefly valuable for placer mining, and that the continued operation of the defendants thereon would result in irreparable injury to the plaintiffs.

Waskey v. McNaught, 163 Fed. 529, July, '08.

DUTY TO KEEP MINE REASONABLY SAFE.

The law as well as the Federal statutes impose upon an owner of a mine the duty of exercising reasonable care to see that the mine is in a reasonably safe condition for miners to work therein. The law does not impose upon the miner the duty of exercising care and prudence to discover the condition of the mine before beginning work. But if the mine is in such a defective or dangerous condition, which is so obvious to the eye of the miner at the time and place as to make it apparently dangerous to work there, and he voluntarily proceeds to work at such place and under such circumstances, without complaint, he assumes the risk and cannot recover in case of injury.

Bolen-Darnall Coal Co. v. Williams, 164 Fed. 665, Oct., '08.

LIABILITY FOR INJURIES TO SURFACE PROPERTY.

The owner and operator of coal mines was held liable in damages for the drying up of the wells of water of the owner and occupant of the surface lands, which resulted directly from the negligent operation of the mines. It was sufficiently shown that cracks and fissures in the surface lands, occurring at the time of the disappearance of the water in the well, were caused by the negligence of the owner of the mines in failing to properly and sufficiently timber and otherwise sufficiently support the roof of the mine.

Sloss-Sheffield Steel & Iron Co. v. House, (Ala.) 47 South. 572, Nov., '08.

SALE OF MINERAL LANDS.

A contract for the sale of mineral lands provided for the payment of a large part of the purchase price from the profits of the mines; by the terms of the agreement the purchaser was to promptly install a reduction plant for the proper treatment of the ores of the mines, and for the diligent operation of such mines to secure the means for the prompt payment of the purchase price; it was expressly stipulated that six months was sufficient time to procure and put the plant in operation; but if by using reasonable diligence it could not be completed within that time, this should be no ground for rescission or damages. It was also agreed that \$60,000 of the purchase price was to be applied to the payment of liens against the property, and the vendor was to furnish a list of all liens. In an action by the vendor to rescind the contract it was held that the vendee's delay of eleven months in installing the reduction plant was not excused because the vendor's title was defective as to an undivided one forty-eighth part of the property, but which defect was not known to the vendee during the delay; and that a mere claim against the vendor was not a valid lien against the property where it was not recorded. Neither was the vendor's failure to furnish a schedule of liens an excuse for delay in building the reduction plant.

Brown v. Gordon-Tiger Mining & Reduction Co., (Colo.) 97 Pac. 1042, Nov., '08.

Publications Received.

Any of the books noticed in these columns are for sale by or can be procured from the MINING AND SCIENTIFIC PRESS.

THE CALIFORNIA EARTHQUAKE OF APRIL 18, 1906. Report of the State Earthquake Investigation Commission. Vol. I. Parts I and II with Atlas.

This is the first volume issued by the Commission, which included Andrew C. Lawson, G. K. Gilbert, H. F. Reid, J. C. Branner, A. O. Leuschner, George Davidson, Charles Burkhalter, and W. W. Campbell. Mr. Lawson, professor of geology in the University of California, is chairman, and to his initiative is due largely this important scientific publication. The volume is a quarto of 450 pages, beautifully illustrated, clearly printed, and well arranged. It is full of interesting information, beginning with a general description of the earthquake and its effects. The rupture of the earth's crust has been traced in a line stretching from Point Delgada to San Juan, a distance of 270 miles. The rift follows an old line of seismic disturbance. The plane of rupture is vertical; the vertical displacement was as much as 3 ft. and the horizontal displacement as much as 21 ft., with an average of fully 10 ft. The zone of destructive effects reached for 35 miles on each side of the fault. Nearness to the fault determined the intensity of the shock, but the character of the foundation was a large factor also, alluvial formations and filled ground being much more severely shaken than the solid rock. Several of the Government buildings in San Francisco stood on 'made' ground; owing to settling, before and after the earthquake, the southwest corner of the Post-Office has been lowered 4.72 inches, the Appraiser's Building is 11.23 in. lower on the south side, and the Mint is 5.97 in. lower also on the south side. The maximum effects were observed near Bolinas and Inverness. On the Shafter ranch the fault-crevice entombed a cow, the fault-trace being a trench 6 to 8 ft. wide. Among minor features it is substantially proved that rumbling, as of a train or rushing wind, preceded the big shock. Visible undulations, more than a foot high, were seen on the surface of the ground. Persons were made dizzy and were nauseated. Among the interesting features of the volume is G. K. Gilbert's discussion of faults and fault-movements. For example, he speaks of voids due to faulting. If two fault-walls should not fit accurately, maintaining contact through part only of their extent, there would be voids. If through a part of their extent they are thus separated, then the walls on the average must be farther apart than before the movement. The book is not for general sale. It is priced at \$15, and a limited number of copies are obtainable from the Carnegie Institution of Washington. The expense of publication was defrayed by the Carnegie Institution and that explains why the book is disfigured by eccentric spelling. This is the only blemish.

ANNUAL REPORT OF THE DIRECTOR OF THE MINT, FOR THE FISCAL YEAR ENDED JUNE 30, 1908. Pp. 265. Washington. Government Printing Office. 1908.

In addition to the usual statistics of precious-metal production, deposits of bullion, coinage at home and abroad, exports and imports, and multitudinous other details, the report of Director Frank A. Leach calls attention to certain interesting metallurgical improvements. The Government is abandoning the sulphuric acid process for bullion-parting and refining, electrolytic refining plants having already been installed at Philadelphia, Denver, and San Francisco. The losses prove to be less than by the acid process, and the recovery of platinum from the gold bullion is a source of profit, although the quantity contained in any one deposit is so small as to render it impossible to account for that metal to each individual depositor except at a loss. Another metallurgical improvement consists in the process devised by David K. Tuttle, refiner at the Philadelphia Mint, for toughening brittle melts of standard gold bullion by the use of cupric chloride. The chlorine reacts with the troublesome base, which is slagged off, while the copper takes its place in the bullion.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

DUMP-CAR.—No. 907,254. Ernst M. Lied, Columbus, Ohio.

In a dump car pivoted upon a truck and having a swinging door, a cam lever pivoted to said car and adapted to be out of contact with said truck when said car is dumped, a hook for said door, a bar connecting said hook and said lever, said lever being adapted to be brought into contact with said truck when the car is righted, whereby said lever is swung upon its pivot to retract said bar and actuate said hook to lock the door.

MOTIVE-FLUID-OPERATED ROCK-DRILL.—No. 907,041. Charles M. Hampson, Denver, Colorado.

The combination with a casing and a drill, of a motive fluid-controlled hammer piston for striking the latter, a drill chuck provided with a ratchet formed on the face of its inner extremity, a pawl-holder mounted to have an alternating rotary movement for rotating the chuck, pawls carried by the said holder, occupying position parallel with its axis, and mounted to reciprocate in recesses with which the holder is provided, the said pawl-holder having differential surface areas, the casing being provided with means for constantly admitting the motive fluid to the smaller surface area of the said holder, and also with means for intermittently admitting the said fluid to the larger surface area, the intermittent admission of motive fluid being controlled by the reciprocation of the hammer, substantially as described.

GOLD-FILTERING MACHINE.—No. 895,599. Thorstein Thordson, Oakland, California.

A gold filtering machine comprising stationary inclined troughs disposed one above the other and spaced apart, one of said troughs being of a greater width than the other and having a side sloping inward, and an air blast means disposed intermediate said troughs and directed toward the bottom and said sloping side of the said wider trough, the upper trough having openings directed toward the lower trough, as set forth.

IGNITING DEVICE FOR MINERS' SAFETY-LAMPS.—No. 908,432. Ferdinand A. Wicke, Barmen, and Rudolf Gartenmeister, Elberfeld, Germany.

In a miner's safety lamp the combination with the lamp wick of a priming composition, a priming band supporting said composition in proximity to said wick, two spindles supporting said band, a medium heated by an electric current and adapted when heated to ignite said composition, a source of current and connections between the latter and said medium.

APPARATUS FOR DISINTEGRATING ORES AND OTHER MATERIALS.—No. 908,861. Harry W. Hardinge, New York, New York.

In apparatus for disintegrating ores and other materials, in combination, a tumbling barrel comprising a conical inlet portion having an inlet opening, and a conical outlet portion joined at its base to the inlet portion and provided at its apex with an outlet opening; a multiplicity of crushing bodies freely movable inside the barrel; and means for supporting the barrel for rotation about its longitudinal axis and with the lowermost side of the outlet portion making a lesser angle to the horizontal than the corresponding side of the inlet portion.

SAFETY-CATCH FOR MINE-CAGES.—No. 907,835. Henry Martini, Pawnee, Illinois.

The combination with vertically disposed guides and stops arranged thereon, of a cage operating between said guides comprising a pair of I-beams rigidly fixed to one another and arranged at the upper end of the cage, the vertical flanges of which I-beams are extended so as to engage the side faces of the guides, blocks removably fixed to the under sides of the I-beams at the ends thereof, sliding blocks arranged on the fixed blocks, the outer ends of which sliding blocks engage with the stops on the guides, and means connected to the sliding blocks whereby the same are moved outward when the hoisting cable of the cage is broken.

Matte-Tapping Device.

By EDWARD J. FOWLER.

The usual methods for tapping matte in copper or lead smelters necessitates the use of a quantity of pots of various styles and sizes. In lead furnace operations it is usual to crush this matte and after roasting return it to the furnace; or if high in grade, it is shipped to the refinery. In copper-smelting plants, the disposition of matte is made by two systems: first, in case the matte taken from the furnace is to be blown to blister copper, the matte must be taken from the fore-hearth or furnace in ladles and placed in the converter while in the molten condition. In the case of copper smelters making matte for shipment or for re-treatment through other furnaces, matte is generally tapped into small pots, allowed to cool, and then broken up and re-smelted direct; or crushed, roasted, and smelted.

The device shown in this article is particularly useful in case of re-smelting matte. A difficulty in tapping matte from a fore-hearth into pots, is that the stream is generally stopped between the filling of each pot, and as these pots hold only 400 to 500 lb., an ordinary small copper-matte furnace will fill four or five small hand pots at each tap-

ped in thin layers, which makes it easy to crush for later operations. The 16 pans hold a total of 3000 lb. of copper matte. After the tap is made, the car is run to the cooling plates, and after standing about 30 minutes the molds are dumped, one after the other. A wrought-iron bar revolves around the centre pin so as to catch these pans for dumping, and the operator has only to put a bar under the back lug and tip it up slightly, when the over-balance will throw the matte from the pan. It is held from going too far by the bar fitting across the back. When three molds are dumped, the operator can throw them back into place by pressing down the top of the pan with a bar. This requires only a few minutes for the entire car. After dumping, the molds are washed with ordinary clay wash, and the car is set in position for another tap. It is possible to tap 3000 lb. every 30 minutes by the use of this car, but it would probably be safer to allow 45 minutes. The cakes are in simple form for handling after they are cooled. With some grades of matte it would be possible to further disintegrate the cakes by pouring a stream of water on them while hot, but this is hardly necessary, as a light tap with a sledge hammer will break the cake, which is only 4 in. thick. The pieces can then be loaded into an ore car. The

life of the pans is good, due to the fact that the hot matte does not strike the pans in such a way as to cause excessive expansion and contraction, and the cast iron is not liable to be overheated at one spot, as in the ordinary matte-pot.

Commercial Paragraphs.

The WESTERN ELECTRIC Co. recently made a record installation of a telephone switchboard at Franklin, Pennsylvania. The old equipment was destroyed by fire, and within 48 hours an emergency board was in service and within 12 days the complete new switchboard was installed and in working order.

The DEARBORN DRUG & CHEMICAL WORKS reports that the general business of the company for the last six months of 1908 was larger than for any other six months in its history, indicating the quick return of prosperous business conditions. The increase during the past six months, and especially for January, in the Eastern department of the company, is particularly gratifying.

EDWARD C. BROWN, manager of the Hawaiian office of the Dearborn Drug & Chemical Works, is making an extensive Oriental trip of three or four months, during which he will visit Japan, the important sea coast cities of China, Australia, the Philippines, Java, and other important islands in the Pacific Ocean.

CHALMERS & WILLIAMS advise that both the Amparo M. Co., at Etzatlan, Jalisco, and the Cherokee Goldfields, Ltd., at Parral, Chihuahua, have recently purchased Burt rapid cyanide filters.

Catalogues Received.

THE NORMAN W. HENLEY PUB. CO., New York, has issued a new catalogue of its scientific and practical books for engineers and artisans, which will be sent free to anyone interested.

The BAUSCH & LOMB OPTICAL Co., Rochester, New York, is distributing a new edition of its catalogue of engineering instruments. This publication is of interest because of the complete specifications given for the optical and mechanical construction of the various transits, levels, and theodolites. The several unique features of the Bausch & Lomb instruments are explained in brief, while an entirely original mining transit is catalogued for the first time. The distinguishing features of this new instrument include a prismatic side telescope. The catalogue is sent gratis upon request.

Dumping From Kilker's Matte Tapping Car.

ping. This necessitates extra work, such as the actual tapping, sweeping up after tapping, and preparing dollys and tapping bars. Also the wear and tear on the pots themselves is heavy. A good cast-iron pot should last nearly a year, but when we consider the expense of this compared to the weight of matte tapped into it, the life of the pot is comparatively short. In order to have a good matte-handling system using pots, it is advantageous to have cast-iron plates around the fore-hearth, and to have a good sized yard in which the pots can cool. After the pots are cold, it is necessary to spall by manual labor, which operation consumes time and is expensive.

The system here described was first used in Montana, and has lately been introduced into the Selby smelter. The car, popularly called a 'merry-go-round', consists of a steel I-beam frame, mounted on roller-bearing cast-iron wheels. The frame-work has a solid steel upright pin placed between the wheels, which carries the weight of the spider and pans. The spider is made in a solid cast-iron piece, and rests on the upright pin, with hardened steel button-bearings at the bearing-point to minimize the friction. On the spider are placed 16 pans, shaped like the sections cut from a pie. Each pan is held in place on the spider by its own weight only, but is prevented from falling outward by a lug cast on the centre of the bottom of the pan. When these pans are full of matte, they may be easily revolved with a bar. The car is run under the tapping spout, and while the tap is being made the pans are slowly revolved, so that the matte falls in the successive pans one after the other, and the entire mold is filled by a series of layers of matte, so that when they are dumped, the matte is found to be solid-

EDITORIAL.

FROM the Geological Survey of Canada we have received three maps covering portions of the Province of Nova Scotia. These maps give accurate information concerning the geological structure of an interesting region, but they are more valuable as an example of conscientious surveying by Mr. E. R. Fairbault.

IN 1908 the mines of the Transvaal yielded gold worth £29,957,610 or \$145,294,408, as against our preliminary estimate of \$144,675,000. The output for December is swollen by about \$750,000 taken from the reserves of gold held by various mines. The increase of yield in 1908 as against 1907 was £2,547,400 or \$12,355,890. At present 9429 stamps are at work, and the general condition of the local mining industry is better than for three or four years past.

ALTHOUGH care in the preparation of statistics is commendable, timeliness also is of the essence of utility in this branch of arithmetic, therefore we look askance at the pamphlet received this week entitled, 'The Production of Silver, Gold, Lead, and Zinc in the Central States in 1907', issued by the United States Geological Survey. More than a year has elapsed since the activities recorded, and while the analysis of the production of these metals may be interesting to a few, it is sadly belated.

THE INSTITUTION of Mining and Metallurgy, London, has decided to add Corresponding Members to its Council. These are residents in foreign countries and act as 'Committee of Council' for the district in which they reside; in addition, they are empowered "to appoint local consultative committees of ordinary members or associates of the Institution to advise on matters referred to them by the Council or on matters of local interest which the committees may themselves wish to submit for consideration by the Council."

WE NOTE that an estimate has been submitted by the Secretary of the Treasury to the Congress for the construction of a fire-proof building to be occupied by the United States Geological Survey and other bureaus in the Department of the Interior. We hope an appropriation will be voted enabling this suggested improvement to be made without delay, for it is high time something of the sort were done. The recent fire in the building now occupied on F street should be taken as a warning of the danger to maps, reports, illustrations, notes, instruments, library, and other records valued at nearly \$5,000,000. Moreover, the building on F street has become so crowded by the growth of the subordinate bureaus annexed to the Survey during recent years that scientific work is

hindered. This crowding, together with the noises admitted from a thoroughfare, renders research and careful study almost impossible. Obviously, a suitable fireproof building with adequate floor-space is required. We hope the Congress will vote the necessary funds.

ENTHUSIASM is always delightful, and this is one of the charming qualities of Mr. Samuel Newhouse. He either believes in a thing or he disbelieves in it; in either case his emotion manifests itself at high tension. Mr. Newhouse believes that the Fink process has come to the copper industry as a metallurgical revolutionary. An insignificant little apparatus is to take crude pyritic ores and turn out blister copper at a single operation of a few hours' duration. We hope it may; we do not know that it will not; but we are sure that the generous patron of Mr. Fink is unprepared to demonstrate as yet that it will. After a single experimental run, before the difficulties and problems that only continuous operation through a long period can bring to light, had enabled the economies of the process to be determined, Mr. Newhouse, jubilant and sanguine, flew to New York, where his own enthusiasm proved contagious enough to enlist capital in a project for erecting large works for the application of the new system of smelting. We wish them well, but we cannot avoid remarking, it's quite too sudden!

MISFORTUNES of varied nature have overtaken the Amalgamated Copper Company during the year just ended. Through fear lest normal production would further depress the price of copper, operations were curtailed in the earlier months of 1908, and devastation by floods in June suspended smelting at Great Falls until September. In view of this the payment in dividends of \$12 per share on the 150,000 shares of Boston & Montana stock, and of \$1.68 on the 1,200,000 shares of Anaconda stock, derived from profits won, must be declared a creditable achievement. It is estimated that copper has been produced by these companies at a cost lying between 9 and 10½ cents per pound. This is an improvement over former results, but still seems excessive. It is not a little remarkable that the mining methods at Butte have not kept pace with the spirit of betterment which the same companies have displayed in their metallurgical departments. At one end the practice is characterized by the extreme of modernity; at the other it suggests the survival of the ways of a passing generation. Current opinion is that the cost of the ore laid on the surface at the greater mines in Butte is not less than \$3.50 per ton. It would seem from this that the chance lay open for shaving the price of Montana copper another cent or two. If publicity in details of mine management were demanded by the stock-buying public, reform in such matters would be hastened.

CURRENT gossip would have us believe that sane business men propose building a cross-country railroad in Nevada to divert the silicious ores of the Goldfield district to Ely for reduction.

The names of W. B. Thompson, and F. M. Smith of borax fame, are linked with this enterprise; only one more name would be needed to reveal the actual purpose in view. It would be difficult to contradict the affirmation that Ely is not circumstanced so as to compete with smelters in the Salt Lake valley, except for basic ores. The extra cost of carrying ore past Ely to Salt Lake, against the freight on coal from Utah to Ely, would be sufficient to determine the superior advantages possessed by the Salt Lake smelters, quite apart from metallurgical considerations. The eastern Nevada ores are highly silicious; the contribution of basic material in the concentrates from that region is wholly inadequate as a compensating flux; the Ely ores as they come from the mine are likewise deficient in bases, and are made self-fluxing by concentration. Closer concentration to reduce the silicious content would involve larger losses of copper. The smelting of silicious custom ores at Ely would necessitate the use of barren lime in the furnaces, and that costs money. Until some contributions of valuable basic ores available at Ely may be discovered, we cannot conceive that the smelter at that point would even welcome the influx of Goldfield ores, and the construction of a railroad to convey them there is preposterous. Moreover the reduction of ores by milling at Goldfield can be done at a lower cost than that of freight and treatment at the smelter. But it is plain that with the Nevada Northern as one link in the north, and the unprofitable Tonopah & Tidewater praying for salvation in the south, the construction of 207 miles of track from Ely to Goldfield would afford the Western Pacific an outlet to the Santa Fé tracks at Daggett, from which point it could doubtless make traffic arrangements similar to those enjoyed by the Salt Lake road for entry into Los Angeles. As the approach to southern California for the Gould system, the building of the proposed trans-Nevada line becomes comprehensible.

The Washoe Decision.

Further details from Butte give emphasis to our earlier comments upon the decision of Judge William H. Hunt denying the injunction against the Anaconda Copper Mining Company, and the Washoe Copper Company. The case is analogous to that decided originally in favor of the Mountain Copper Company in California, in which the ruling was based on and equity, and the good of the general public was held superior to the advantage of a single individual. The eminent fairness of the Montana decision appears in the fact that, while denying the injunction sought, the petition is held to warrant further hearing to ascertain whether means may not be found to prevent continuing damages from arsenic. It has been demonstrated that small losses of live-stock occur from the settling of this substance over the pastures close to the smelter. Substantial damage from sulphur-fume since the erection of the new stack has not been proved. The plaintiff contended that the flue-gases contained 10.9 milligrams of arsenic per cubic foot, at which rate it was computed that no less than

48,100 pounds of arsenic per diem were emitted from the stack. This would reach the enormous total of over 8000 tons per year. Such a volume of so active a poison would inevitably endanger the lives of the inhabitants of Deerlodge valley, and would render cattle-raising in the zone of the prevailing smoke-drift quite impossible. In winter the condensation would occur immediately and imperil the health of operatives about the works. Arsenic is completely solidified in fume at from 70 to 80° C., or at about 167° F. The smelting company replied that the quantity of arsenic claimed by the plaintiff to issue daily from the stack was in excess of the total quantity present in the ore smelted, the larger portion of which was known to be caught in the arsenic plant attached to the works.

In addition to the fact that the industries of Montana would suffer a staggering blow from the closing of the Washoe smelter, the methods pursued by the farmers in attacking the copper company savored so strongly of what can only be defined as blackmail that the test case brought by Fred J. Bliss was seriously weakened. Combinations for protection violate the rules of society when they impose conditions of settlement with the alternative of a threatened suit at law. When it transpired that the plaintiff was so tied to the Farmers' Association as to be unable to compromise with the smelting company, the case smacked of conspiracy with unfair ends in view. When finally it was proved that the plaintiff could at any time rent the land to dairymen, the plea for relief necessarily fell to the ground. The Court held that under the circumstances the plaintiff should be content with the remedy open through trial by jury to recover for past damages. A hearing will be given on February 15 to ascertain what reduction of the smoke-trouble can be effected. The plaintiff claimed that the temperature in the stack 50 feet above the base was 189° C. If this were true, it would be plain that the gases would carry arsenic and sulphuric anhydride in large amount. As sulphuric anhydride begins to precipitate at about 150° C., and as deleterious quantities of arsenic cannot remain in the fume at 100° C., there would seem to be opportunity for the smelter effectually to put an end to this vexing and costly controversy.

Colombia.

In round numbers, Colombia has yielded \$700,000,000 to the world's stock of gold. As Mr. F. Lynwood Garrison points out elsewhere in this issue, that quantity of metal has been obtained almost entirely by crude washing of alluvial deposits with the batea and by 'booming' or ground-sluicing. Modern appliances have not been employed; hence this gold has come only from gravels of extraordinary richness. That fact alone is significant of the possibilities for operations on a large scale by modern methods. Mr. Garrison appears to be justified in concluding that when the resources of Colombia are properly developed the returns will be such as to make that Republic the greatest gold producer in the world. The gold district lies principally in the western por-

tion of the country, in the valleys of the Cauca and the Atrato. The most extensive placers are in the Cauca valley, beginning at Quilichao, in the Department of Popayán. From that point the gold-bearing gravels are continuous for a distance of 400 miles toward the north. Nowhere in the world exists a gold-field of equal extent. Moreover, the tributaries of the Cauca, fed by the rains and snows of the high Sierra, offer unlimited opportunities for the development of electrical power in every part of the gold-bearing territory. Of nearly equal extent are the goldfields of the Department of Quibdó, occupying the northwestern corner of the Republic, from Cali to the Caribbean Sea, within which is included the famous Chocó with its placers of gold and platinum. Aside from these riches in the royal metal, Colombia possesses one of the largest coal districts in all the Americas. Coal is found from the Ecuadorian frontier to the Caribbean, and from the plains of Bogotá to the Pacific. At Pacho, near Bogotá, is a modern iron furnace and rolling mill, the Fundición de Hierro la Pradera, smelting the ore mined within sight of the works with coke made from coal beds close-by. In the territory bordering the Caribbean, chiefly in the Department of Santa Marta, are evidences of large deposits of iron, coal, and petroleum, as yet undeveloped. Copper is reported throughout the great central Andean chain as far south as the Territory of Caquetá, and it must be borne in mind that both fuel and water-power are ever present to facilitate the development of these deposits. The great immediate need is improvement in transportation facilities. In the days when Mr. Blaine's infectious confidence in the immediate response of South America to the engines of progress set so many adventurers concession-hunting at the Spanish-American capitals, a few commendable enterprises were started in Colombia. Mr. S. B. McConico undertook to develop the possibilities of the magnificent port of Cartagena by a railroad which had an empire of opportunity before it: the railroad reached the Magdalena river, and left the opportunities to one side. Mr. W. B. Cherry died before his line from Buenaventura reached Cali. A few interior lines, furnishing outlets to the Magdalena river for Bogotá and Medellín, together with the little Sabanilla-Barranquilla road, constitute the whole of the railway development in the Republic, and it must be said that the country has paid dearly for the few miles of track which her subsidies have called into existence. But from the signs of vigor and sanity in the present Administration, wiser governmental policies will hereafter prevail. What has been done in Mexico will be repeated in Colombia. The period of government by revolution seems ended there under the wise guidance of President Reyes, and the lure of gold and the opportunities for the basal industries of civilization must soon bring this neglected country to the front. It is a country friendly to American enterprise, in spite of the occasion for resentment offered by the flagrant violation of the territorial integrity of the Republic by our Department of State joining with revolutionaries for the secession of Panama.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. W. MUDD is in New York.
W. A. FARISH is at Los Angeles.
ALBERT BURCH is at Kellogg, Idaho.
H. W. TURNER is in southern Nevada.
E. P. MATHEWSON was recently at Cananea.
EDGAR RICKARD was at New York this week.
SCOTT TURNER is now at Kennett, California.
H. L. TWITE has returned to London from Bolivia.
HENRY BRELICH has returned to London from Manchuria.
HENRY W. LAKE has returned from Manchuria to England.

H. VINCENT WALLACE, of Nogales, Arizona, is at New York.

HENRY TAYLOR, of John Taylor & Sons, is in Tasmania at present.

THEO. F. VAN WAGENEN is at New York, on his way to Europe.

L. C. GRATON is about to resign from the U. S. Geological Survey.

HENRY KRUMB was recently at the Ray mine, near Kelvin, Arizona.

J. MALCOLM MACLAREN is on his way to Kalgoorlie, Western Australia.

H. S. WIERUM has been appointed consulting engineer to the Lewisohns.

J. E. MCALLISTER, manager of the British Columbia Copper Co., is at New York.

G. E. ALEXANDER, of Denver, spent the greater part of the winter traveling in Mexico.

C. W. BOTSFORD, of Guanajuato, has been examining mines near Alamos, in Sonora, Mexico.

W. L. CUMMINGS, of the Bethlehem Steel Co., was recently at Alamos, Sonora, Mexico.

PEARCE & PARKER have opened an office for assaying and engineering at Alamos, Sonora, Mexico.

WILBUR A. HENDRYX, of Denver, has left New York and gone to Arizona on professional business.

T. LANE CARTER is in Nicaragua, examining mines. His address is, Care of American Consul, Bluefields.

JOHN E. ROTHWELL has been ill for several weeks past, and is now recovering from a serious operation.

J. W. FETHERSTONHAUGH, lately superintendent for the Goldfields of Mysore Co., has returned to London.

GEORGE A. SCHROTER was recently at the mine of the Creston-Colorado Co., at La Colorado, Sonora, Mexico.

F. S. NICHOLLS is no longer connected with the Famatina Development Co., although he reported on the smelting plant.

E. McCORMICK, of Calumet, Mich., recently passed through Chicago, on his way to examine property in Washington and Oregon.

WALTER G. PERKINS has accepted an appointment as metallurgist to the Tanganyika Concessions, Ltd., and will shortly proceed to Africa.

ANDRÉ P. GRIFFITHS and E. A. MANNHEIM have entered into partnership as mining engineers and mine managers, at 781 Salisbury House, London.

HENRY M. ADKINSON, manager for the Gold Pioneer Co., at Telluride, Colo., has returned to Denver from a business trip to Chicago, Boston, and New York.

CORTLANDT E. PALMER has changed the style of his professional card, but this does not mean any change in his relations with the three companies by whom he is retained as consulting engineer.

General Mining News.

ARIZONA.

GILA COUNTY.

Work was resumed on Friday, January 29, at all the mines in the Globe district which closed down five days before. There was no interruption in smelting during the month, so the 'late unpleasantness' between the operators and the miners' union has fortunately not been a very serious affair.—The Arizona Commercial Copper Co. is carrying on development at the Eureka shaft and at the Black Hawk workings. At the latter a raise is in progress to connect the 550 and 500-ft. levels. When this is completed, a hoist will be installed to sink a winze from the 550-ft. level in the west drift, where an orebody 38 ft. wide has been cross-cut. The station at 710 ft. in the Eureka shaft will soon be finished, and as soon as a larger station pump arrives a drift will be started at that level, which is expected to run into another orebody. Grading for the smelter is well under way.

PIMA COUNTY.

A pleasing report has been addressed to the shareholders of the Twin Buttes Mining & Smelting Co. by the directors.

Map of Arizona.

They have cleared off an indebtedness of \$75,000, and left a good cash balance; the superintendent, McDermott, has discovered several excellent orebodies; and the usual weekly shipments of 8 carloads have brought good returns from the smelter at El Paso. The company now has about 60 men at work in the mine.—The Grand Central mines, near Tucson, consist of 10 mining claims, on which the vein outcrops prominently for a length of about 1500 ft. In the vein are three shafts with several drifts and cross-cuts, which have exposed not only gold and silver ore, but a valuable deposit of vanadinite, the vanadate and chloride of lead. George H. Daily is manager.

PINAL COUNTY.

Sherwood Aldrich, the president of the Ray Consolidated Mining Co., states that the company expects to break ground by the first of July for the new mill at Ray, the capacity of which will not be less than 2000 tons per day, and possibly as large as 6000 tons; that the company now has 10 to 12 million tons of ore in sight, running about 2½% copper, which can be mined very cheaply by the caving system;

and that the building of a smelter is a certainty later on, but not immediately.

E. Feltman and H. Quinn have brought back from their claims near Helena some fine specimens of cinnabar, which they found at a depth of 14 ft. This is believed to be the first discovery of quicksilver ore in the region. The claims are situated on Hot creek, and are eight miles due north of Helena.—A. G. Cadogan and S. Rothschild, superintendent and general manager, respectively, have tendered their resignations to the directors of the Homestake-King Mining Co., of Bullfrog, to take effect February 10, when S. B. Tyler will assume entire charge.—The total output of the Tonopah mines for the past week was 4608 tons, of an estimated value (the shipping ore being valued at \$60 per ton and the milling ore at \$25 per ton) of \$115,200. The Tonopah Co. sent 2500 tons, the Belmont 600 tons, the Montana-Tonopah 708, the Midway 100, the MacNamara 300, West End 100, and Jim Butler 300 tons to the mills, making the total shipments for the week to the mills 4608 tons.

YAVAPAI COUNTY.

The Santa Maria Gold Mining Co. has been taken over by some mining men of Utah and Montana. George B. Weaver and J. F. Cowan have been examining the property, on which 1400 ft. of development work has been done, and recommended the purchase of the property to their clients. Among others interested are H. C. Weaver, of Salt Lake, and M. S. Browning, of Ogden.

CALIFORNIA.

INYO COUNTY.

The mining men of the northern district of Inyo county are well pleased with the completion of the Southern Pacific cut-off, by which it is rendered possible to ship ores to tidewater at San Pedro; the distance is from 200 to 300 miles, and cheap water transport can usually be got thence to the northern smelting regions. These conditions have added vigor to the mining developments of the county.—A company of Los Angeles capitalists is making a number of exhaustive tests of the graphite and iron deposits in Mazuka canyon. The company intends, if these minerals meet requirements, to erect a plant to use the graphite and hematite as a base for a mineral paint.—George H. Farish, of Denver, is making a thorough examination of the Cady & Reed copper property in Eureka valley.

NEVADA COUNTY.

The Gold Flat, Pittsburg, Potosi, and the extensions of the Gold Flat and Pittsburg mines have been consolidated into one big company, named the Pittsburg Gold Flat Mines Co. The consolidation means the opening up of the properties on an extensive scale. Joseph Weissbein and Mark B. Kerr have arrived to take preliminary steps looking to a resumption of work at the properties. The officers of this new company are: Joseph Weissbein, president; Mark B. Kerr, vice-president and manager; Frank Sperling, secretary; S. L. Ackerman, Samuel Granger, and W. H. Martin, directors.

SHASTA COUNTY.

The Rough and Ready mine, owned by Edward Bracket and situated in the Lower Springs district, has been sold to the Shasta Mining Co. for \$20,000. The final payment was made during the past week. This mine was one of the steadiest ore shippers to the Keswick smelter during the operation of that plant.—The equipment has arrived at the Gladstone mine, near French gulch, for an electric line to transport ore from the mine to the 20-stamp mill.

SISKIYOU COUNTY.

Forty-two mining locations have been made since the new year on Klamath river, between Happy Camp and the Humboldt county line. The total area is 3600 acres, which was staked out by nine men, presumably for dredging purposes. These are the same men who last year located numerous mining claims on Klamath river, above Happy Camp.—The big dredge at Callahan started up on January 4, after repairing their bucket line. It is the intention of the company to put in a complete new bucket system this summer.

—Elliott & Co., operating the Finley hydraulic mines at Sawyers bar, have their pipes and giant laid and are now piping off surface dirt with two crews. They hope to be able to get to their pay-gravel by the opening of the spring months.—Charles Johnson, the Six Mile creek placer miner, is handling a large body of gravel with his self-shooter and has washed out some good sized nuggets.

COLORADO.

CHAFFEE COUNTY.

Leadville parties are negotiating to take up the Bradbury discovery, made last summer near Granite. Bradbury has made several shipments of gold ore, and is desirous of interesting local capital.

LAKE COUNTY.

The stored-up waters of the Resurrection mine on Little Ellen hill are now pouring into California gulch through the Yak tunnel. When the breast of the drift from the Yak reached a point approximately 35 ft. from the old workings a diamond-drill hole was started to tap the water. In order to guard against all possible contingencies J. R. Champion, the superintendent, placed a valve in position to control the flow, and a pressure of 250 lb. to the square inch was registered. It is believed that this will lower the water in the Resurrection at the rate of a foot per day, and effect complete drainage before May 1.

OURAY COUNTY.

The last annual report of the U. S. Geological Survey gives the total output of the mines of the county in 1907 as nearly three million dollars. The Sneffels district produced over 97% of the gold, nearly four-fifths of the silver, approximately three-quarters of the lead, and over 91% of the total values of the metal output of the county; and the Camp Bird mine produced nearly \$600,000 more in value than any other mine in Colorado during the year.

SUMMIT COUNTY.

The adit of the Pitt Ores Co. has broken into a new orebody below the old workings. The mill recently erected at the mouth of the adit is completed and is now ready to handle all the ore that is produced.

TELLER COUNTY.

At the annual meeting of the shareholders of the Cripple Creek Drainage & Tunnel Co. all the directors were re-elected except S. S. Bernard, who is succeeded by A. L. Burris to the presidency. The treasurer showed that of the total of \$388,500 subscribed toward the tunnel, \$175,000 is still due. The company has \$23,819 cash on hand and has paid for all work up to January 1, 1909, so that it has nearly \$200,000 with which to carry on the work. It is estimated that about \$120,000 additional will be required to complete the tunnel. Of the total of 15,500 ft. to be driven, 4872 ft. had been completed in the three headings to January 1 and 246 ft. bored this month, making a total of 5118 ft. to date.—The New Pearl Gold Mining Co. has just incorporated under the laws of Arizona, and intends to work the Log Cabin vein on Mineral hill; it also has bonds on the Laura Lee and New Pearl claims, the owners of which are F. J. Campbell, J. F. Wood, and F. L. Sigel, of Denver.—Four carloads of machinery have arrived for the Wishbone mill. J. H. Whalen, representing the firm of Chisholm & Matthews, of Colorado Springs, has come to the district to superintend the erection of the Edwards roaster, and stone masons are already at work on the foundations. The new roaster will have a daily capacity of 100 tons and will be used for the refractory ores.—Sinking is in progress in the main shaft of the Strong Gold Mining Co., at Victor, and will be continued to the 1100-ft. level, or until water prevents further sinking. This level will correspond with the 1500-ft. level of the Portland No. 2 shaft, the deepest of the Battle Mountain district. It is believed that the ore-shoot under development on the main Strong vein, at the 1000-ft. level has proved the richest orebody disclosed to date. The mine is shipping an average of 4 cars per day to the Golden Cycle mill at Colorado City. The total produc-

tion of the Strong mine is not published, but it is a matter of record that the company had paid out in dividends \$2,475,000 to the close of 1903. At a conservative estimate the company will have distributed not less than \$3,500,000 in dividends to date.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—The ore in the Alice mine, on which a strike was made last summer, continues to hold out well and to improve. Recent assays give 40% lead and 30 oz. silver per ton. The principal owners are Richard Wilson and Walter McKay, of Portland, James F. McCarthy, of the Hecla mine at Burke, and Fred N. Russell, of Seattle. They will start work for a new concentrator within two months if the ground be free from snow.—A cave-in of part of the upper workings took place in the Tiger mine, owned by the Federal Mining & Smelting Co. at Burke, but no material damage was done. The accident took place about 100 ft. from the Tiger mill. The mine had just been abandoned by the Federal company and the greater part of its machinery installed in the Standard mine at Mace. The shipment of ore is still being continued by lessees.—Before the close of the summer upward of \$100,000 will have been spent on the H. E. M. property in Revenue Gulch district. The recent strike made on the property has turned out admirably, and it is the intention of the company to erect a concentrator and begin mining and shipping. In the meantime a contract for 400 ft. of work has been let to C. D. Roberts, of the C. & R. property at Burke, the terms of which demand that not less than three shifts be employed. At the same time the force of men in the upper workings has been materially increased.—At a recent meeting of the directors of the Ajax Mining Co. it was decided to double the force of men at work on the property, and arrangements have been made accordingly. This action is taken in view of the splendid showing in the drift which has now been run about 1600 ft.—A report of the affairs of the Copper Plate Mining Co. has been issued. The finances of the company are in fair shape considering the fact that the mine has been under steady development for months past, having done about 2200 ft. During the year \$6300 was spent in development, while a balance of about \$500 still remains on hand. The annual meeting of stockholders has been called, and steps will be taken to raise funds for the continuation of the work.—All arrangements have been completed by which the Success mine, operated by H. F. Samuels, of this city, will resume operation on April 1. A considerable amount of ore is blocked out ready for treatment so that both mine and mill will resume operations at the same time.—The strike made in the Black Horse mine in the Murray district some time ago has now widened out to about 7 ft., practically all of which is clean shipping ore. The ore was encountered in a drift at a depth of about 1000 ft.—A good record has been made by the contractors in the development of the Hector Mining Co. on Canyon creek. During the past 30 days 140 ft. of progress has been made, of which 92 ft. was in hard rock, not a single timber having been required in the mine. Ore is showing in small quantities, but nothing of commercial value has yet been found.

Wallace, January 30.

NEVADA.

ESMERALDA COUNTY.

The National Ore Purchasing & Reduction Co. has started the grading and foundation work for its custom mill in the town of Rawhide. The machinery has been shipped, and includes rolls, Graupner centrifugal quartz-mills (which will reduce the ore to 80-mesh), and a Bertram Hunt slime filter. This last is a continuous type of filter designed to separate the gold-bearing cyanide solution from the pulp, and will be the first one of its kind ever installed. J. W. Heisner is president of the company, and L. M. King is manager.—The second annual report of the Goldfield Consolidated Mines Co. for the year ending October 31 shows that the company had \$911,000 in the treasury, after expending

approximately \$900,000 on mill, railroad, and pipe-line construction. The water supply stored on Columbia mountain is equal to running the mill for 10 days in the event of a break in the Lida pipe-line. Actual saving on the plates, it is claimed, has been 94 to 97%. Cost of mining, milling, and transportation has been reduced from \$11.27 per ton to \$8.81, with a prospect of a further reduction. Concentrates that cost \$30 to \$50 per ton to ship and smelt are now treated at home for \$5 per ton. The total production for the year shows 32,755 tons of \$41.50 per ton; and 12,254 tons of second-class ore have been placed on the dump, worth \$7.76 per ton. The gross value of ore produced was \$2,400,191, and it is hoped that the operation of the new Combination mill will effect a saving of \$2,000,000 per year.

What may become an important turquoise mine has been discovered in the vicinity of Crow Springs, by John Kennedy, who was formerly a plumber's assistant in Tonopah. The find was made at a point nine miles southwest of Blair Junction, and occurs in black limestone veins, the widest of which is about ten inches at the surface. Several small shipments have been made to Tiffany of New York.—The statement issued today by the secretary of the Florence-Goldfield Mining Co. shows that the company has expended during the year 1908 the sum of \$344,240, in addition to paying out \$420,000 in dividends. The total earnings for the year were \$515,708, and the balance on hand at the beginning of the year was \$131,769. This statement is disappointing when compared with that for the first six months of 1908, which showed a cash balance of \$690,000, when the new mill was understood to have been fully paid for.

EUREKA COUNTY.

The mining camp at Windfall is four miles south of Eureka; it was worked many years ago, producing much silver and lead. A low-grade silver-lead ore is now being shipped to the Utah smelters at the rate of 300 tons per day. For, while the value is less than \$10 per ton, yet a reasonable profit can still be made. A new ore deposit has recently been discovered in a different formation, which carries gold; and it has been found to be perfectly amenable to the cyanide process.

LANDER COUNTY.

Placer operations on an extensive scale will begin within a few days at Ione, 115 miles north of Goldfield. The managers are putting in some two miles of pipe-line, and a Fairbanks-Morse pump. They claim that their gravel is worth over \$1 per cubic yard, and that there is an abundance of it. The controlling interests are Thomas D. Murphy, E. R. Collins, and D. D. Muir, all of Goldfield.

LINCOLN COUNTY.

William A. Farish has examined the properties of the Nevada-Utah Mines Co., at Pioche, for the president, George E. Learned, who states that the developments have been very satisfactory. The ore faces at the 900-ft. level are all showing a higher grade of ore than on the 800. They have run into a copper vein that gives 4% copper and 20 oz. silver, while in the silver-lead orebody they have struck a shoot yielding 100 oz. silver and 50% lead. Though the output is now limited to a production of 50 tons per day, the underground workings are in good shape to produce 200 tons in that period.

NYE COUNTY.

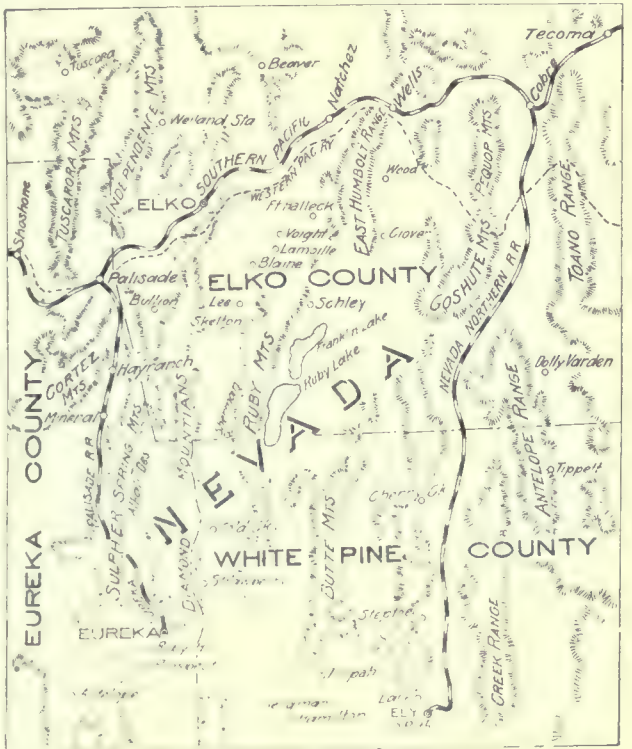

The Melvin and the Monster claims, at Round Mountain, have both been producing tungsten ore, and Dr. Gohlin is endeavoring to consolidate the claims and make arrangements for milling the combined output. Some tests have already been made by Henry E. Wood & Co. of Denver, and the concentrate produced was purchased at the rate of \$10.20 per unit.—News comes from Tonopah that during the past week the Jim Butler property shipped to the Belmont mill at Millers, 300 tons of milling ore. The orebodies on the first level average about three feet in width, and the stopes on the second level are showing five feet of good quality ore. On the intermediate level the vein is still producing the high-grade ore.—The directors of the Round Mountain Mining Co. have decided to increase the capacity of the mill

to 110 tons per day. A compressor with 10 drills will be added; also one tube-mill. The present production is \$30,000 per month. The average cost of treatment is \$5.40, but the improvements will doubtless reduce this. All the levels are in ore from 3 to 14 ft. wide, and the backs are estimated at \$1,000,000. On March 18 the fourth quarterly dividend will be declared, absorbing \$32,000.

John R. Nolan, George R. Fanshaw, Alonzo Oxsley, and C. W. Merryfield, of Spokane, have taken over seven claims in the Clifford district, 50 miles northeast of Tonopah. The first two are on the ground doing assessment work. The Clifford mine in the same district was located by Edward and James Clifford, of Spokane, who took out \$30,000 two years ago, selling the property afterward to the Broken Hills Mining Co. for \$350,000. Merryfield says that a railroad has made a survey through their property and that the line may be built in 1910.

STOREY COUNTY.

A fire in the Sutro tunnel destroyed about 700 ft. of the timbering between the Combination and Consolidated Virginia shafts on the night of January 27. T. F. McCormick, superintendent of the Ophir, and Bernard O'Hara, superin-

Map of Eastern Nevada.

tendent of the Sutro Tunnel, state that the fire raged in the north lateral, and that the tunnel was burned to the Combination connecting drift. The shafts were not damaged. In some places the tunnel caved, and for a time it was feared that the water would back up to the Ward and Consolidated Virginia shafts. Bulkheads were placed in the north lateral and the fire was quickly got under control. Estimates of damage are not yet certain, but so far as is known the damage has been comparatively small. The stocks of the companies involved dropped from 10 to 50%, but recovered most of this loss during the next day.

OREGON.

BAKER COUNTY.

Thirty-three miles of the railroad from Huntington to the Iron Dyke mine are completed, and trains are running down Snake river to the mouth of Powder river. At the Ox Bow bend, about five miles above the Iron Dyke, 400 men are employed in the construction of an electric-power plant with a capacity of 25,000 hp. Both the power company and the railroad company are putting on all the men they can get, and 2000 men are employed on bridge work, driving tunnels, and grading for the ties and rails. The

Iron Dyke mine is at Homestead, which will be the terminus of the railroad. Large quantities of copper ore are said to be awaiting shipment on the completion of the road.—Samuel Newhouse, of Salt Lake, recently took over the controlling interest in the Rainbow mine here. This is a free-milling gold property in Mormon basin.

UTAH.

JUAB COUNTY.

A cave occurring on the 230-ft. level of the East Tintic mine has displayed to the manager, Ralph Kellogg, some good grade silver-lead ore, which is believed to be a continuation of the vein developed by the 130-ft. level.—Sinking is still in progress at the Bullock mine, near Silver City; it is the intention of the management to drive under the ore exposed in the old workings on the 200-ft. level.

TOOELE COUNTY.

Work has begun at Tooele City to do the grading for the new road of the International Smelting Co. to Pine canyon, where a smelter is to be built. By building a spur from the Salt Lake route at Tooele City the company has but $6\frac{1}{2}$ miles of work to do. Steam will be used upon the road for the first two years, after which it will be equipped with electric cars. The plans are not yet completed, but it is the company's intention to install the smelter with a capacity of 2000 tons.

WASHINGTON COUNTY.

The Virgin River Oil & Development Co. has not as yet had much success in the search for oil in payable quantities. But there are now good indications of a 40-ft. petroleum zone at a depth of about 1200 ft. Unfortunately several of the rigs have dropped their boring tools and are engaged in a 'fishing job.' Among others operating are the G. I. Hastings Co., the Virgin Valley Oil Co., managed by S. A. Halterman, the Grafton Oil Co., and H. H. Clark.

WASHINGTON

STEVENS COUNTY.

(Special Correspondence).—In the Metaline lead district, mining is dull, as the mines are confronted by several difficult problems. It was thought at one time that the ore of this district could be more profitably handled in a concentrated form, and the Spokane Lead Mines Co. erected a concentrator to treat the product of its mine, but owing to the character of the ore and to financial trouble, this mill was only run a short time. Early in 1908 the stockholders of the Morning and Mammoth mines formed a company, known as the Morning-Mammoth Concentrating Co., and this concern took a contract to mill the ore from the two mines named, but for various reasons this concentrator has never been set up, although some of the machinery is on the ground. One of the valuable constituents of Metaline ore—the lime gangue—is lost in the process of concentration, so that this ore is of more value to the smelters in its original state than after concentration. It is thought that a solution of these problems is offered in the starting up of the Panhandle smelter, on Lake Pend d'Oreille and the building of the Washington & Idaho railway into the Metaline district. Metaline ore is desirable for this smelter, and with a reasonable smelting and freight rate it is believed that this low-grade ore can be shipped at a fair margin of profit. The average low-grade ore of this district carries about 10% lead, while in the shipping ore of better grade 4 to 8 oz. silver and some gold are found, as well as a higher percentage of lead.—The Keller & Indiana Smelting Co. has acquired some additional property to that held by the company heretofore, and is accumulating ore and fuel at the smelter preparatory to blowing in this plant.—A new company, capitalized at \$1,500,000, has taken over the Republic mine, at Republic, from the county, which acquired it through delinquent taxes. A force of 30 men is being worked, and a small compressor and some electrical machinery have been ordered and should be at the mine early in February. A car of ore recently shipped returned the company \$74 per ton. The ore is being treated by the Granby smelter. The new owners of the Republic seem sanguine

in their intentions to make the Republic a paying mine, but they will no doubt have to contend with many of the difficulties that the old company encountered in handling the refractory ore of this mine.—Mining men who are heavily interested in the Granby Consolidated are now developing the Holden mine, in the rich Chelan Lake district of central Washington. The Holden is a huge low-grade deposit, and will make another mine similar to the Phoenix, B. C., mines now being worked by the Granby Co. Railway facilities are lacking in the Chelan district just now, but it is understood that plans are under way for the building of a road into that district as soon as development of the mines has progressed far enough to warrant the necessary expenditure. The Chelan Butte Gold Mining Co. owns three valuable claims in this district, and is now taking ore that carries \$150 per ton in gold from the 200-ft. level. The company has 150 sacks of high-grade ore ready for shipment which will average \$6 to \$7 per sack of 70 lb.—Coal mining is the principal branch of the mining industry of this State today, and the Roslyn district is the most extensively worked field. Five new and independent companies have opened up mines in Roslyn district during the last eight or nine months, all of which are increasing their capacity as rapidly as possible. The coal of this field is a superior domestic product and is in great demand. Nearly 66% of the coal production of Washington is consumed by the railway and steamship companies. The Northern Pacific Railway Co. owns many valuable coal mines and produces about 44% of the entire output. The coal output for 1907 was 3,713,824 tons, valued at \$7,427,648; about \$2 per ton. The coke produced amounted to 61,400 tons, value \$276,300, or about \$4.50 per ton. The figures for 1908 have not yet been completely compiled, but are expected to exceed those for 1907 by a good amount. North of the Roslyn coalfields there are large areas of valuable iron deposits that will one day be an important factor in the manufacturing industry of the State of Washington. The possibilities of these vast fields of coal and iron, lying so near to each other, are manifold, and hold forth much of promise for the mining industry of the State of Washington, which is as yet only in the first stages of development.

Spokane, January 28.

The Delmonico mine, three miles east of Chewelah, which was recently taken over by the New Dominion M. Co. at a total cost of \$25,000, has received the first consignment of machinery from Spokane. This is a duplex plunger pump, capable of handling 85 gal. per minute. The shaft is now 120 ft. deep, and will be sunk 300 ft. farther. The company has ample finances.

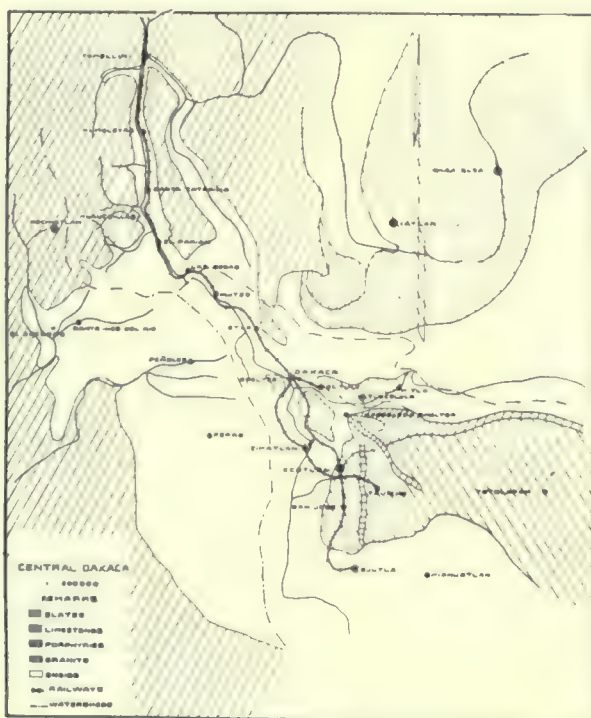

CANADA.

BRITISH COLUMBIA.

A company is being formed with a large capitalization to take over the 27,000 acres of coal lands on Graham island, acquired from a Victoria syndicate by the firms of Tracksell & Butler, and Gray, Hamilton, Donald & Johnson, of Victoria. An application is now before the legislature for a charter for a railway between Skidegate and Rennel sound to open up the mining district. The Victoria company, which has held the coal property since 1885, includes William Wilson, C. H. Todd, Capt. John Irving, Robert Tennant, Major Nichols, T. T. Gore, Dr. G. L. Milne, W. A. Anderson, and others.

The British Columbia Copper Co. took advantage of the forced close-down last week, through lack of power, to make some necessary repairs to the smelter plant, thus obviating a close-down later on. Only two of three furnaces have been in commission during the past week, but it is expected the full battery will again be operating in a few days.—The Canadian Pacific railroad has struck gas at a depth of 1900 ft. at Bow island in the Medicine Hat gas field. The flow is estimated at 1,500,000 cu. ft. per day.—The cable for the tram line which the owners of the Golden Eagle mine are building from the property on Volcanic Mtn. to the Kettle Valley railway, has been received at the mine, and it is expected that the tram will be in operation

in about six weeks.—It is reported from Winnipeg that a strike of the British Columbia and Alberta coal miners may take place after March 31, on which date the two years' agreement between miners and owners comes to an end. The men demand a rate of increase which the operators do not consider reasonable to allow. About 2,000,000 tons are produced annually by the Province of British Columbia alone.—Mineralogists have been puzzled by the appearance of ore from the Republic mine, which more resembles house-plaster than anything else; it carries free gold, but so fine as to be invisible to the naked eye. The mineral petzite has also been found, and some carload lots have netted \$65 per ton from the Grand Forks smelter. An abundant tonnage has been broken, and a good profit assured, as freight and treatment rate only amount to \$6.50 per ton.—The first payment on the Knob Hill mine was made on December 29. The purchasers are capitalists from Philadelphia, Pennsylvania, represented locally by S. L.

Map of Central Oaxaca.

Boyer. They have completed about 1000 ft. of development since taking the option last spring; installed a compressor and made a great many other improvements. Boyer will assume personal charge upon his return from the East.—According to J. L. Warner, manager of the Kootenay Belle mine, in the Nelson district, that mine will immediately increase its capacity by 10 additional stamps. The present production with four stamps is \$5000 per month.

MEXICO.

W. R. Ramsdell, president of the Tenamache Mining Co., who recently returned here from the States, has just placed an order for reduction machinery for the Tenamache mines near Zopilote, Tepic, with the International Machinery & Engineering Co. of Mexico City. The order covers 10 stamps, re-grinding machinery, concentrators, cyaniding equipment, gas producers, and electrical equipment. It is planned to operate the machinery by electricity generated by the gas engines. The machinery will be delivered at the Pacific port of San Blas in time for its transport to the mines before the opening of the next rainy season.—L. C. Malone, of the Tajo Mining Co. (Jalisco), reports satisfactory progress in the development of the mine. The Las Boquitas orebody is exposed 7½ ft. wide, and assays 1100 gm. silver and 9 gm. gold, without sorting. The winze is showing up well, carrying 11 gm. gold, besides silver. Malone is not altogether pleased with the progress in the mill construction, as some of the necessary machinery got stalled at Etzatlan.—The Indé Gold Mining Co., Durango,

have struck a deposit of free-milling gold-ore, which will add considerably to the supply available for its mill, the present capacity of which is 100 tons per day.—J. L. Saint Dizier, manager of the Encinillas Smelting Co., of Sta. Rosalia, has at last started the first furnace at three-quarters of its ultimate capacity, and will soon have it at full blast when the water supply is improved. This French company has contracts with the Naica to supply 2000 tons of ore per month.—When the Esperanza at El Oro has installed its 10 tube-mills for fine-grinding, the company will re-work its tailing heaps, which at present are merely washed by spent solutions.—The El Oro Mining & R. R. Co. has abandoned the use of imported pebbles in tube-mills and now uses hard quartz ore in rough 3-in. cubes; 53 lb. of these cubes, and 0.2 lb. of liner are abraded per ton of sand ground. The same company also made Christmas presents of half a month's pay to those employees of more than one year's standing.—The 50-stamp mill of the Amparo Mining Co., in the Etzatlan district, has been crushing 140 tons per working day. The value of the ore treated has been 433 gm. silver and 11.2 gm. gold per metric ton, and the total gold and silver extraction is reported as 92.8%. The company has lately declared a dividend of 2½% for the quarter.—The Mexican Copper Co., operating the Magistral claims in the Ameca district, State of Jalisco, has been incorporated in Washington by Patrick Clark, of Spokane, and his associates, for \$1,500,000 in \$1

Palmarejo, Chihuahua.

shares. A 2-compartment shaft has been sunk to a depth of 500 ft., and various drifts have been made in gold and copper-bearing ore. J. J. Stewart says that when these have been further developed the company will install a complete machinery plant.—The managers of the Palmilla mine will largely decrease the cost of pumping, and of extraction of their ore some time in April, when they expect to complete their drainage tunnel. Driving is being done with air-drills from both ends and progress is at the rate of 3 metres per day.—The Cinco Minas, in the Hostotipaquillo district, are being satisfactorily developed by Henry E. Crawford for the Marcus Daly interests; and it is now understood that a 5 or 10-stamp mill will be erected as a preliminary to the building of a 300-ton plant.—The Philadelphia Copper & Gold Mining Co., operating the San Vicente group of mines at San Martin Hidalgo, in the Ameca district, has cut a vein of the group in the No. 4 tunnel. An assay taken over a width of 6 ft. shows a value of \$12. The manager, M. J. Slattery, now has a large tonnage of ore developed.—News from the State of Oaxaca informs us that the Denny Bros. of South Africa are examining the San Martin gold and silver mines, near Ejutla.—Howard A. Kelly has acquired the entire holdings of the Oaxaca Milling Co. The mill is to be a custom mill for the treatment of ores of the Taviche camp, and will be completed as soon as the tests show the proper treatment. The mill when completed will cost about \$300,000.—J. W. Brill, of the Tapada y Victoria mines, in the Tototlapam district, has purchased complete equipment for a 10-stamp mill.

Special Correspondence.

NEW YORK.

Fink Furnace. — International Smelting. — Nickel Alloy. — Railroad from Tonopah to Ely.

Copper men are evincing great interest in the operation of the new Fink furnaces at Garfield, Utah. Samuel Newhouse, who is financially interested in the Fink patents, when in New York recently, stated that the initial trials of the furnaces were very satisfactory, and his enthusiasm for the new copper reduction process was so contagious that he succeeded in obtaining large financial assistance for erecting new smelters in Utah and Nevada, on copper properties he is interested in. These plants will be equipped with Fink furnaces, which are of the rotary type. Two such furnaces, capable of revolving at different speeds, and in opposite directions, are connected together. Fuel, such as oil, charcoal, sawdust, coke, or coal, is charged into one furnace, and the flame and gases are conducted to the next one. The object of such an arrangement is to permit the completion of smelting, bessemerizing, and refining in one operation. While the charge in the first furnace is being smelted and refined, the charge in the other furnace is roasted by the flame and heated gases from the first furnace. When the ores are rich in sulphur, very little extra fuel is required, and with suitable ore, the cost of smelting will be much below that of the ordinary hot-blast furnace.

The directors of the recently formed International Smelting Co. are busily engaged in completing the purchase of copper mines and smelters. During the past week they purchased the mines and smelters of the Compañía Metalúrgica de Torreón, Mexico. The price paid has not been divulged. It is stated, however, to have been high. The smelter, which has a capacity of 1500 tons per day, was owned by Mexicans, with Ernesto Madera as president. The Mexican company was capitalized at \$2,500,000, and its stock sold at \$150. Purchases of mines and smelters in the Western States involving the expenditure of \$20,000,000, will be announced in the course of a couple of weeks.

The International Nickel Co. is taking advantage of the low price of copper to promote the sale of its nickel-copper alloy called Morrell metal. This alloy is composed of 70% nickel and 30% copper; it is suitable for use in boiler-tubes and in all places where corrosion of steel or iron may occur from steam or water. The company's smelter at Chrome, New Jersey, is working full time on Canadian ore. In addition to the demand for nickel for coinage purposes, and for plating, there is a large demand for alloys and for armor-plate. The company continues to pay 1½% quarterly dividends.

Those connected with the Tonopah & Tidewater Railroad Co. and the Nevada Smelting & Mines Co. are arranging to send out a new survey party to lay out the projected railroad from Ely to Tonopah. Recent developments at Ely, Tonopah, and Bullfrog have led interested capitalists to undertake the construction of the road immediately, before others grasp the opportunity. The Standard Oil people have invaded the Ely field and purchased controlling interests in the Giroux Consolidated, Cumberland Ely, and other mines. They have also purchased large interests in Utah copper mines and intend making Ely a great copper smelting centre. There will, consequently, be good prospects for those first in the field in building railroads connecting the copper and gold districts of Nevada and Utah, with Ely. The new Ely-Tonopah road will be about 207 miles long, and will cost \$4,000,000. The completion of the road will reduce the carriage of Tonopah ores to the smelters by over 270 miles, the Steptoe plant benefiting at the expense of the Garfield smelter.

The New York mining market has been in a depressed condition since last October. In that interval there was very little activity in mining stocks of any kind, except Cobalt. Owing to syndicate operations the stocks of certain

companies operating in the Canadian silver field were advanced a few points on several occasions, but even Cobalt stocks are now dull. At the present time, however, there is a stronger tendency in the market, and it is generally believed that activity will soon be noticed. The outlook is improving, notwithstanding the condition of the iron, steel, and copper industries. Speculators and investors feel that with general trade once more exhibiting prosperous signs, and with money abundant and cheap, they are warranted in again turning attention to mining. Many new schemes are being projected, and these will, probably, be shortly advanced by a return of activity in mining. The recently incorporated International Smelting Co. is active in purchasing mines at present, but rival companies will soon be in the field.

LONDON.

West Australian Dividends. — Le Roi, British Columbia. — Investigation of Cornish Mines.

Last week I submitted a list of dividends paid by the Rand mines during 1908. Similar calculations in connection with West Australian gold mines show that the dividends declared during the year have amounted to £1,424,362, which is a decrease of £227,156 compared with 1907, and of £565,465 compared with 1906. The largest sum distributed during any year was in 1905, when the dividends amounted to £2,079,324, though the figures for 1903 and 1904 were practically no lower. The drop in 1908 is accounted for largely by the impoverishment of the Oroya-Brownhill mine. Five years ago, Lake View Consols and Great Boulder Perseverance were also great producers, but they have now become low-grade properties. During 1908, Great Boulder Proprietary heads the list of dividend payers with a distribution of £262,500. Then follow Golden Horseshoe and Ivanhoe, with £240,000 each. After these come Kalgurli with £165,000 and Great Fingall with £166,250. These five are the only mines that have distributed over £100,000. The other chief dividend payers are the Associated Northern Blocks with £87,500, Associated Gold Mines with £86,688, and Great Boulder Perseverance with £70,000. The Great Boulder Proprietary, the Ivanhoe, and the Golden Horseshoe have reserves of ore that promise many years of prosperity. Decreased treatment-costs have made it possible to keep some of the impoverished mines going, and in one or two mines a better quality of ore has been met with, but, generally speaking, no important developments of ore deposits have been made in West Australia during the year.

As an example of the work done on low-grade ores at the present time in West Australia, the case of the South Kalgurli Gold Mines, Ltd., may be mentioned. This mine lies immediately to the west of the Great Boulder Perseverance, with the Kalgurli and the Great Boulder Proprietary on the north and south, respectively. Operations commenced in 1899, and for three years the ore yielded about one ounce per ton. The ore then changed in nature and value, so that new plant had to be provided, which was started in the summer of 1905. The treatment now consists of roasting, fine grinding, cyaniding by agitation, and filter-pressing. The amount treated during the 12 months ended September 30 last was 105,169 short tons, and the yield was 34,079 oz., valued at £144,459. The average yield was approximately 6½ dwt. per ton, equal to 27s. 6d. per ton. The working costs are given in great detail by the manager. The average mining costs come to 6s. 7½d., and the metallurgical treatment to 12s. 4½d. per ton. Development expenses were 2s. 9½d. per ton of ore milled, bringing up the aggregate costs to 21s. 9d. The total mining and treatment costs were £103,197, and of development £14,685. In addition, £1656 was spent in equipment, and £8222 allowed for depreciation. London and other general expenses came to £2733, leaving a profit of £15,549, out of which £10,000 has been distributed as dividend, which is at the rate of 5%; £5500 was written off the cost of development work in previous years. Great care is exercised in the study of costs, and continual improvements are being made. The costs for mining and

metallurgical treatment during November were only 18s. 2d. per ton, as compared with 19s. 0d. during the year ended September 30. The amount of ore reserves on September 30 was 121,868 tons, averaging just under 7 dwt., in addition to which there is probable ore estimated at 95,000 tons, averaging over 6 dwt. It is expected that in the future 5-dwt. ore can be worked at a profit.

After working for a year or more in rather poor ore, not sufficient to earn a profit, a better grade has been found in the Le Roi mine at Rossland, B. C., in the lowest or 1650-ft. level. Developments are being continued to open up these bodies of ore by means of winzes, and the ore now being shipped to the Northport smelter averages about \$20 per ton. During the year and a quarter ended September 30 last, 100,444 tons were mined and smelted, the average content being $7\frac{1}{4}$ dwt. of gold, 0.55 oz. silver, and 1.22% copper. At the current price of metals the average value of this ore was \$11.11 per ton. The loss on the operations was £24,895. The funds in hand on July 1, 1907, amounted to £154,509, and after deducting the loss mentioned, the directors have decided to write off the whole of the balance of mine-development account, amounting to £35,106, and the cost of options, £5475, two items left as part of the legacy of confusion from the old extravagant days. The balance to the credit of profit and loss account is therefore reduced to £89,032. The outlook at the mine is on the whole unchanged from what we have been accustomed to during the last few years, though of course the discovery of better ore at the lower levels is encouraging. On the other hand, the low prices of copper and silver are adverse factors, and ore with higher gold content is what is sought after. During the last year the services of W. A. Carlyle have been of value to the mine, in his capacity as consulting engineer. It is interesting to note that Mr. Carlyle's appointment to the professorship of metallurgy at the Royal School of Mines will not interfere with his professional practice in connection with the Le Roi or other mines.

The presence of an outside mining engineer in Cornwall is always to be welcomed, for it infuses new ideas. It is therefore of interest to note that your special contributor, R. Gilman Brown, is now studying the North Levant and Geevor properties, situated near Lands End, close to the Botallack and Levant mines. The mines belong to a company the control of which is with the same group as are interested in the Ymir mine in British Columbia, a mine that enjoyed Mr. Brown's services as consulting engineer for some time. Mr. Brown has acted in the same capacity for North Levant and Geevor and has recently joined the board. Mr. Oliver Wethered, chairman of the Ymir and of North Levant and Geevor, is also a director of Dolcoath and Wheal Vor, so that he has a close connection with Cornwall, and his introduction of Mr. R. Gilman Brown into the county is of special interest.

Mr. Brown came to the conclusion that too great a quantity of barren rock was being mined and milled at North Levant and Geevor. Accordingly he stopped development while arranging an improved method of mining. In the meantime the mill treated accumulated ore from the stopes and ore from the old dumps. On the chief orebody there is a shoot 400 ft. long and about 13 in. wide that carries 175 lb. of tin oxide per ton. Even when the lode is mined together with the necessary rock on either side, the ore milled can be brought to 60-70 lb. of tin oxide per ton. On another lode, the ore mined is about 45 lb. of tin oxide per ton, and the prospects in several parts of the mine are excellent. A new and up to date dressing-plant has been erected, consisting of two heads of Holman's air-cushion stamps (I do not like the name 'pneumatic stamps,' as it seems to be misleading), together with Frue vanners and Wilfley tables. The two heads together crush 50 tons of ore per day, and during October the cost of crushing and dressing ore came to 4s. 4d. per ton. While writing of Mr. R. Gilman Brown, I should mention that he is also investigating the Dolgelley copper mine, in North Wales, where the Elmore vacuum process is used for concentrating the copper ores. Mr. Wethered is a director of this company also.

ROSSLAND, BRITISH COLUMBIA.

Le Roi Report.—Power Interruptions.—Proposed Legislation.—B. C. Copper Co.—Silver King Abandoned.

The annual report of the directors of the Le Roi Mining Co., Ltd., recently read at London, shows a debit balance to profit and loss account, on the operations of the Le Roi mine and smelter for the 15 months ending September 30, 1908, despite the substantial profits earned during several months of the past fiscal year. The increase shown in the cost per ton of ore mined was caused by the heavy fixed charges being spread over a smaller tonnage shipped than during the previous year. The sum of £9701 was written off for depreciation. The company also paid off part of the indebtedness to the bank during the year. In arriving at this balance of profit and loss account the following amounts were also written off: for exploration and development, £27,108; sundry items of expenditure, £3995; the whole making a total of £40,804. The liabilities of the company on September 30 are shown as £65,326 and the assets amounted to £95,792, showing a surplus of liquid assets over liabilities of £30,466. This is considerably lower than for the previous fiscal year when the surplus of liquid assets over liabilities was £74,260; so that the report taken altogether is not one to delight the heart of a shareholder. There are some redeeming features, however, particularly in that portion of the general report contributed by A. G. Larson, the resident superintendent. During the fiscal year under review the Le Roi mine produced 100,444 dry tons of ore which averaged 0.363 oz. gold, 0.55 oz. silver, and 1.22% copper, figuring \$11.11 per ton. This ore was richer than that produced in 1907, which carried 0.29 oz. gold, 0.44 oz. silver, and 0.98% copper, giving an average value of \$10.49, or 62c. per ton less than during last year, even though during part of 1907 abnormally high prices were obtained for most of the copper and silver produced. It is estimated that the ore produced during 1908 was worth about \$1.40 per ton more, on an average, than during the previous year. It contained about 5 lb. more copper than in the previous 12 months, but the cost of extraction was greater, since much of the ore was taken from the smaller stopes in the mine. The Northport smelter produced 2780 tons of matte, having a value of \$1,164,912, or \$418.97 per ton. The smaller tonnage treated ran the costs up a shade at this point also, the fixed costs in connection with the smelter being heavy. It is a moot question whether or not the company would not be better off to swallow the bitter Northport smelter pill, dismantle the works there, and ship the product of the Le Roi mine to the Trail smelter, where it is said a rate can be obtained that is much cheaper than the cost of treating Le Roi ore at Northport. The Le Roi mine last year produced enough good ore to pay dividends to the shareholders, but with the fixed expense of the smelter and of the London office the balance is on the other side of the page. While it is impossible to adjudge fairly without knowing all the inside facts it looks to an observer as though it would pay the shareholders to dispose of the Northport smelter and the London office, with attendant traveling expenses to and fro. It would be safe to wager that the financial statement of the company would show a good profit in a comparatively short time.

During the recent spell of zero weather the power-plant of the West Kootenay Power & Light Co., at Bonnington Falls, was compelled to stop work for several days owing to trouble with the slush and ice in the Kootenay river; as a consequence the mines of Rossland and the Boundary district were compelled to cease operations for the better part of a week, which will result in a lessened production of ore from these districts for January. Being closed down many of the mines undertook repairs, which will cut into the profits to quite an extent. The Le Roi No. 2, Ltd., during the month of December shipped 1995 tons of ore from the Josie workings, from which the smelter receipts were \$24,759, and 73 tons of concentrate, from which the company received \$744.

At the eleventh annual convention of the Associated

Boards of Eastern British Columbia, to be held at Trail, resolutions will be introduced by Nelson and Kaslo representatives, suggesting that the leases on mineral claims cease at noon instead of at midnight as at present; that "in contemplation of the production of spelter in quantity by the new electric process now operating at Nelson, B. C.," representations be made to the proper Dominion authorities toward the necessity of a re-arrangement of the duty upon zinc products entering Canada and "to the necessity of seeking, through the medium of Canadian trade channels, possible markets abroad." These are the principal resolutions that will be proposed which affect the mining industry.

About 250 men are working in the Mother Lode of the British Columbia Copper Co. This is a much larger force than the company finds it necessary to work underground in the summer when glory-hole mining is more easily carried on. Ore of greater richness is extracted from all of the big Boundary mines during the winter months than during the summer. The reason is that the ore is more carefully picked from the different stopes, and there is a better opportunity to sort it than when thousands of tons at a time are broken down in the glory-holes. This feature is an important factor in mine accounting in the Boundary. It is stated by P. F. Roosa, manager and provisional liquidator of the Dominion Copper Co., that he expects to see work resumed at the company's mines in about six weeks. The machinery at the Boundary Falls smelter is being kept in good condition, so that work may be started without delay. The pumps have been kept going in the mines since the cessation of work so that there has been no accumulation of water.

At Nelson the unwatering of the Silver King mine from the fifth to the tenth levels is being rapidly accomplished, and as soon as this has been finished the force will be augmented and development continued on a larger scale. There is little doubt that the Silver King can be made to pay if untrammelled by the Nelson smelter, which has been a losing business for a long time and has dragged the mine down with itself. The bond which F. A. Erlund and associates have had upon the Queen Victoria mine was released the other day when a payment of \$15,000 became due. This was a surprise to local mining men, as nearly \$60,000 had already been spent by the operators and the Queen Victoria has been looked upon as one of the coming low-grade mines of the district. The deposit is the largest low-grade copper mass in this district aside from the Rossland mines.

BUTTE, MONTANA.

Copper Production. — Smoke-Case Decision. — British-Butte Claims Sustained. — Gold-Dredge Started. — Calumet-Corbin Capitalized on Options. — Mine Protective Legislation. — Concentrating Plant.

With the Boston & Montana Co., the largest producer of copper operating in the district, closed for 11 days during the month, the Butte mines produced 26,502,608 lb. of copper in January, or nearly 2,500,000 lb. less than was produced by the district in December. The different companies contributed to the totals of ore mined and copper produced approximately as follows:

Companies.	Ore, Tons.	Copper, Lb.
Boston & Montana	70,000	5,250,000
Anaconda	112,840	7,108,920
Butte & Boston	20,770	1,287,740
Washoe	17,050	1,023,000
Parrot	12,555	728,190
Trenton	13,578	760,368
North Butte	43,400	3,992,800
Butte Coalition	38,750	3,138,750
Original	28,055	2,188,290
Pittsburg & Montana	8,370	627,750
Miscellaneous	4,960	396,800
Totals	370,328	26,502,608

The average daily output of ore from all the mines was 13,188 tons, and of copper, 948,068 lb. The yield of copper per ton of ore was, approximately: Boston & Montana, 75

lb. per ton; Anaconda, 63; Butte & Boston, 62; Washoe, 60; Parrot, 58; Trenton, 56; North Butte, 92; Butte Coalition, 81; Original, 78; Pittsburg & Montana, 75.

In deciding the Washoe smelter-smoke litigation, and refusing to close the big Washoe smelter by injunction, Judge W. H. Hunt of the United States Court removed a depressing cloud that had hung over the copper mining industry in Montana for four years, and put new life and courage into the mining community. He does not deny a remedy to the 107 farmers who tried to close the mines and smelters, upon the continued operation of which 100,000 people directly and indirectly depend for a living, but he holds that the damage done to the farms is infinitesimal compared to the general damage that would result by the issuance of the injunction. He holds that if the farmers have suffered damage on account of the smelter-smoke, they have a sufficient remedy at law, and that the company is able to respond in damages. As a fact, however, Judge Hunt has found that comparatively little damage has been done by the smoke, and practically none is being done now. He finds that the Amalgamated Co. has been striving constantly to improve conditions and to lessen the damage from smelter-smoke, and that the farmers, in order to bolster up their case for injunction and to force the company to settle with them on their own terms, used as exhibits a number of heads of livestock that were sickened years ago, and for which the company had paid in damages the full value of the stock. These poor specimens of horses and cattle were, nevertheless, kept by the farmers and exhibited to Judge Hunt himself when he visited the farms during the trial of the injunction-suit, as evidence of what the farmers were suffering. Judge Hunt observed that, aside from these particular specimens, the finest looking live-stock he ever saw in Montana thrived in the 'smoke zone'. The farmers had demanded from the company that the latter purchase outright all their lands, improvements, and so forth, setting a valuation on the property of \$1,120,731, representing 90% of all the lands in the Deerlodge valley and in the smoke zone. Against this stands an investment in the smelter alone of \$10,000,000, while all of the city of Anaconda and 60% of the city of Butte are directly dependent on the continued operation of the smelter and the mines. The judge also finds that the company pays 51% of the taxes of Deerlodge (Anaconda) county, and about 30% of all the taxes in Silver Bow (Butte) county. Because of these and other facts cited, the court held that there would be no equity in the granting of the injunction. The decision also is an effective reply to the representations that had been made to President Roosevelt a few weeks ago, that the smoke was destroying the timber on the National Forest Reserves, which prompted the President to take steps to order injunction proceedings against the smelter, which order was afterward recalled. The evidence now brought out disclosed that some arsenic still escapes from the chimney of the smelter and does some damage, and Judge Hunt will personally conduct another investigation, beginning February 15, to ascertain whether this damage can be lessened. The officers of the Amalgamated will do everything possible to assist the court in this inquiry. The company has had several high-salaried experts engaged for several years in studying the problem in all parts of the world. Every improvement at the Washoe smelter has been made on the recommendation of these experts, and enormous expense has been incurred to abate the trouble.

The long contest over the applications of the British-Butte Mining Co. for patents to six of its placer claims at Rocker, west of Butte, has been decided by the special agents of the Interior Department sent to Butte last year to conduct an investigation. The charges of the Government were not sustained, with the exception as to four of the claims, on which insufficient work had been done before application for patent was made. Since then, however, the work has been done, and it will only be necessary to renew the applications. The gold dredge was started Saturday, January 31, with spectacular ceremonies, presided over by Governor Norris and a brass band.

The re-organized North Butte Extension Development Co. is again in trouble. It has been stated that the new company had paid \$30,000 on the options, but that only \$5000 has been paid, and the long promised resumption of work has not yet taken place.

The Calumet-Corbin Mining Co., one of the latest concerns organized to do business in the Corbin district, has already offered its stock on the Eastern curbs, although it does not own the property on which it has been organized and capitalized for \$1,500,000. It has a long-time option on the old Minnesota mine, on which, it is reported, a payment of \$2000 has been made, and not another payment need be made until next fall. The Minnesota was considered worked out many years ago, but the present owners hope to develop new orebodies.

A most important bill is pending before the legislature of Montana to protect and promote legitimate mining enterprises. It will be made a felony for anyone to sell stock

MEXICO.

Purchase of Torreón Smelter.—Price Paid.—Probable Policy.

Report comes from New York that the International Smelting & Refining Co., the new company which is supposed to be a competitor of the American Smelting & Refining Co., has purchased the smelter and mines of the Torreón Metallurgical Co. for \$3,000,000. This will include the smelting plant at Torreón, Coahuila, Mexico, the mines and mill of San Diego, at Santa Barbara, State of Chihuahua, the lease on the Cabrillas mine, near Saltillo, Coahuila, and other smaller mines, and leases in the northern part of the Republic. It is known that some month ago L. D. Ricketts and E. P. Mathewson were in Mexico and visited or examined the properties of the Torreón Metallurgical Co., which is largely controlled by Ernesto Madero, its president, and it is not at all improbable that a sale has been consummated, but the price named seems absurd to those familiar

Map of Mexico.

in a company that does not own the property on which the capitalization is based, unless it is specifically stated and represented that the company is but a leasing company and does not own property. Several years ago a number of mining companies were floated on leases and bonds and options, but the public did not know it until the stock was purchased and the promoters had forfeited the options, leaving the deluded and defrauded stockholders to 'hold the sack'. The companies and their officers protected themselves behind the excuse that they did not represent that they owned the property.

The Butte-Montana Mining Co., owner of the Alex Scott mine, is contemplating the erection of a concentrator at the mine. It is proposed to change the capitalization from 1,000,000 shares at \$1 par, to 125,000 shares at \$10 par. If the stockholders consent to the change, the necessary capital can be obtained.

The stockholders of the Butte & London Development Co. have elected the following directors: Frederick W. Baker, representing the English interests in the company, James A. Talbot, W. W. McDowell, W. E. Reynolds, A. A. McMillan, James H. Lynch, Fred White-side, T. H. Emery, Guy W. Stapleton, and E. J. Anderson, all of Montana. Splendid progress is being made by the East Butte Mining Co. to place that property on a paying basis.

with the conditions. About three years ago, at the summit of the Torreón company's prosperity, the stock was quoted at \$150, with 35,000 shares, or a then valuation of \$5,250,000. At that time it was reported that the American Smelting & Refining Co. was negotiating for the Torreón smelter, and it was generally understood at the time that \$4,500,000 had been offered, but that \$5,000,000 was demanded. The A. S. & R. Co. continued work on the Velardeña plant, not far distant from Torreón, in the State of Durango. Since then the stock of the Torreón company has continually declined, until on the day when the above-mentioned sale was reported it was quoted at \$80. This makes a total valuation of \$2,800,000. It is not probable that the interests behind the International Smelting & Refining Co. would pay \$3,000,000 for what could be had for less than half that figure. That the sale was consummated at a much lower figure is not improbable, for the smelter of 10 stacks is not a bad one, and some of the mines are of enough merit to be attractive to the buyer. The time was propitious then for the transaction. If it has been carried through, it is hard to predict how the smelting business may be affected. Up to the present the independent companies have worked amicably with the A. S. & R. Co., and it is not probable that a new concern, even though fortified with immense capital, can afford to enter the field with a cut-throat policy.

PIOCHE, NEVADA.

**Ore-Shipments.—Lead-Zinc Discoveries.—Smelter for Bullionville.—
Prince Mine.—New Management at Day Mine.**

In the late seventies a prominent mining man at Lake City, Colorado, said: "The San Juan country must soon begin shipping, or stop blowing." Fifteen years later I rode on horse-back through San Juan with a mining engineer, then manager of the great Enterprise mine at Rico and the Yankee Girl at Red Mountain, each with millions to its credit. This mine manager, then also State Geologist of Colorado, had traveled around the globe studying ore deposits and examining mines, and I was deeply impressed with his remark, "Where in the world could one find a mining region of greater interest or promise than this?" San Juan had 'made good'. Its Smuggler, Enterprise, Sunnyside, Guston, Virginus, Yankee Girl, Ute & Ulay, Golden Fleece, and a hundred others, had shipped. Its promise has since been further fulfilled in the Camp Bird, Gold King, and other mines of lesser note. Similarly, Pioche in its early period was a great producer, but we are interested now in its loudly heralded renaissance. It is time for Pioche to begin shipping, stop blowing, or tell the reason why.

The year 1908 opened in a serious financial stringency, with metals declining and markets depressed. To secure money for development was nearly impossible. Every smelting company in Utah, except the A. S. & R. Co., had been put out of business by the courts. The A. S. & R. Co. was not overlooking such opportunities, and advanced its treatment charges to exorbitant and in some cases to prohibitive figures. The Salt Lake railroad made Pioche liberal concessions in freight rates. The A. S. & R. Co. promptly absorbed the benefit, and more. Under such circumstances, mine owners in the camp considered it sounder policy to keep their ores in the ground than to take them out. During the year considerable development was done, but the entire year's shipment from Pioche was only 12,000 tons. This tonnage came principally from the Nevada-Utah's Day mine, the Bristol Consolidated, and the Mendha. The Boston & Pioche, Highland Mary, and Prince Consolidated each shipped a few cars. Not a pound of ore has gone out from the old hill south of town, which made the reputation of the camp in the early seventies. There are known ore-shoots of great value in the ground on that hill, which the Nevada-Utah owns exclusively, but considerable development and more equipment will be required before these can be extracted. The rest of the hill the Nevada-Utah and Ohio-Kentucky companies own between them. There is a tangle of titles which can be unraveled only by litigation or compromise. As matters now stand, for either of them to begin shipping would invite litigation. Negotiations for a compromise have been under way for several months. Until these are definitely concluded the general public will not be admitted to confidence. Another element of moment affects the question of shipping. In the Susan Duster mine the Ohio Kentucky Co. has found between the surface and the 400-ft. level an enormous tonnage of lead-zinc ore carrying silver. Any economic solution of the problem to fit present metallurgical practice will involve a plant for mechanical separation of the ore into lead and zinc products. If such a plant can be erected near the Susan Duster, the lead product could be utilized for a smelter at Bullionville, 12 miles north of Pioche. The Prince Consolidated Mining & Smelting Co. owns the Prince mine, and also the old tailing stored at Bullionville. These tailing-beds were carefully measured and sampled some years ago by Richard H. Browne of Salt Lake, who reported 170,000 tons, carrying over \$2,000,000 in gold, silver, and lead. The great tonnage in the Prince mine runs low in silver and lead, but carries a high excess in iron and manganese. Many other ores of this region carry lime in large excess. The Prince Consolidated is controlled by the same interests that dominate the Ohio Kentucky. These interests have been devoting their attention mainly to planning a smelter

at Bullionville, where the lead from the Susan Duster, the iron from the Prince, the silicious ore from the Mendha, and the lime ores of the district, could be assembled and smelted with the old tailing. The plan is logical, and will probably be worked out with some modifications.

At present everything on the hill is closed tight, and probably will remain so, awaiting a compromise. When that is effected it will involve a lead-zinc separating plant which will treat the lead-zinc ores of the Nevada-Utah as well as those owned jointly by the Nevada-Utah and Ohio Kentucky. As generally occurs in ore-shoots having rich silver-lead ore near the surface, the companies that mined here in the early days found lead-zinc ore in their lower workings. From what can be learned of the records of those days, it is warrantable to believe that an enormous tonnage of lead-zinc ore will yet come from those old mines. This, as well as the recently discovered lead-zinc ore from the upper horizons in the Susan Duster, must all be treated in local plants; at least they must be enriched by mechanical concentration.

Those familiar with the conditions here believe that one of the largest zinc industries in the United States will some day be developed in southern Nevada, but Pioche will not have to wait for that. Until a zinc plant is erected in this county, zinc concentrate can be profitably shipped to outside markets. Up to last summer the Prince was being developed as a low-grade proposition. One day a cross-cut, driven by Wm. Lloyd from the third level for general results, cut a vein carrying silver chloride and lead carbonate. This discovery gave an entirely new outlook for the property. Further exploration on the second, third, and fourth levels has demonstrated not only the continuity for 200 ft. vertically and 300 ft. longitudinally of the vein above-mentioned, but it has disclosed two other veins. In this case the theory so fondly cherished by the prospector has been verified. The veins have grown richer and wider with depth. On the fourth level, from a vein 8 ft. wide in places, they have taken out in ton lots ore running over 1000 oz. silver per ton. No stoping has been done, and only a portion of the ore taken from the drifts and raises on these veins has been brought to the surface. Three 50-ton cars have been shipped, but the returns have not been made public. The treasury of the company has abundant money for immediate needs, and the management has announced the intention not to ship ore in quantity until a spur track shall bring the railroad car to the mine, and until other conditions are more favorable. Meanwhile development proceeds. The main shaft has been sunk, and a cross-cut is being driven from the 550-ft. station toward the rich veins.

James P. Gaskill, chief engineer and general Western manager of the Nevada-Utah, has during the past year devoted his entire attention to the Day mine, 15 miles northwest of Pioche. After shipping several thousand tons of ore as a test and means of studying the conditions of ore occurrence, he stopped shipping and opened the mine by what is known as the Onondago shaft. The collar of this shaft is so situated that the cars run from it 100 ft. and dump directly into the ore-bins. Here the ore is loaded automatically into the company's narrow-gauge railroad cars. Formerly it was sent down on a wire tram. The ninth level connects with this new shaft. All the ore comes through that level and up the shaft. A compact well arranged power-house at the shaft completes the plant. Mr. Gaskill says that when all arrangements are perfected for normal production he expects to put ore into the cars at Pioche for 75c. per ton. J. A. Gallagher was appointed by Mr. Gaskill as mine superintendent last October. Mr. Gallagher will be remembered as the man who was called from the Cumberland-Ely a few months ago to superintend the rescue of the miners imprisoned in the Alpha shaft of the Giroux mine, at Ely. On December 31 L. Webster Wickes resigned his position as general superintendent for the company, and his duties were assumed by Mr. Gaskill and Mr. Gallagher. Shipments were resumed January 2, and a 50-ton car has gone out regularly each day since.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Engineer as a Financier.

The Editor:

Sir—In your issue of January 9, in discussing under the above heading your comments upon Mr. Hammond's recent essay on professional ethics, J. R. Finlay illustrates the difference between purely technical and commercial engineering reports by quoting from the technical report of Engineer Smith and the commercial report of Engineer Brown, both reporting on 160 acres of coal land of Farmer Jones. It cannot be thought that the illustration is based upon an actual occurrence, and we must assume that it was formulated merely to illuminate the difference between essentially technical and essentially practical engineers. For this purpose it may be allowed to stand; as between engineers it will not be misunderstood; but that the financial and commercial world may not be misled as to what happens when an engineer undertakes to advise his clients upon the financial and economic aspects of coal-mining investments, and for the protection of engineers who specialize in coal-land examinations and in the appraisal of coal-land values, it seems essential that the illustration used by Mr. Finlay be properly explained.

While the mining of coal involves fewer uncertainties as to mineable quantities and has certain elements insuring greater stability than the mining of most other minerals, yet the risk and uncertainties that affect the cost of mining, the commercial risks ever present in selling coal, in collecting outstanding accounts, and in transporting coal to market, are such that few capitalists would for an instant consider the purchase of coal property at a price which at best would be returned with compound interest at 6% after a period of ten or eleven years. Yet this is 'Brown's' advice: that the property in ten years will produce a gross profit of \$250,000, and that its present money value is \$125,000. After one experience with 'Brown', his clients would find it more profitable to employ 'Smith', study his statements of fact, and draw their own conclusions as to money values.

In reporting upon coal lands, the engineer usually has a distinct understanding with his clients as to the nature of the desired report. The determination of what should be covered by his report is seldom left to the engineer. If the report be made for coal operators or corporations contemplating purchase, a monetary appraisal of value is rarely required or desired; the clients in such cases usually wish merely to have the facts as to quantity, quality, and mining conditions (faults, etc.), being themselves able to deal with the economic questions involved in the transaction. If the examination be made for owners who desire to sell, an appraisal may not be needed, this being left to the judgment of the purchaser, and to the ability of a shrewd middleman to lead the pur-

chaser to appraise its value at the highest attainable price. If, however, the investigation be made for purchasers who are not practical coal men, or if the report is to furnish a basis for a bond or stock-issue, appraisals of value and estimates of yearly and aggregate profits, and of the life of the property, are generally needed. Before undertaking a coal land examination it is usual for the engineer to come to an understanding with his clients as to the scope of the proposed examination and report. In my own experience this always has been a simple matter, for I have found that my clients usually know exactly what they want the report to cover. Unless an appraisal of value be desired, or advice must be given based upon such valuation, no engineer will gratuitously make an appraisal; for the determination of the present money-worth of coal lands is the most difficult problem for those devoting themselves to this branch of mining work.

The formula 'Brown' offers as applicable to properties that can be worked out in ten years is of seductive simplicity; thus,

Let x = present money value.
 a = tons of mineable coal.
 b = profit per ton.

then

$$x = \frac{ab}{2}$$

'Brown' hesitates to commit himself definitely only upon one point, and that happens to be the one thing of which he should be most sure. He says that, in his judgment, the "farm can be depended upon to produce 1,000,000 tons of coal," but states positively that it can be mined for \$1 per ton, can be sold for \$1.25 per ton, can be worked out in 10 years at a total profit of \$250,000; and says he computes its present value at \$125,000. Variations in market price, competition with other fuels, and other producers, car troubles, strikes, lawsuits, accidents, explosions or other mine disasters, variation in freight rates and in the wage-scale, must ever prevent the appraisal of coal land upon any such basis. With the normal interest rate yielded by good, or even 'gilt-edged' investment securities ranging from 4 to 5% per annum, no coal property which (barring accidents or revolutionary change in economic conditions) presumably can be exhausted in 10 years can be appraised at a value upon which it will return only 6% compound interest. If 'Smith' had been asked to include an appraisal of value, statement of yield, mining profit per ton, and the like, his report might have read about as follows:

"As the ash-content of the coal is high, namely, 10%, the coal will not make coke good enough to command ready sale at satisfactory prices. If coke is to be made, the coal must be washed, and this will increase the cost and may not produce an article of satisfactory quality. In the absence of coking and washing tests, I therefore advise that the coal be marketed as a steam and heating fuel. Competition in the general market with other better coals will probably keep the profit normally down to between 10 and 20c. per ton, except in times of great industrial activity or during coal strikes in other districts.

The property will yield an aggregate tonnage of between 1,100,000 and 1,200,000 tons, based upon a yield of 1200 to 1300 tons (of 2000 lb.) per foot-acre, which, under fairly efficient management, will certainly be realized. It will not, in my judgment, be safe to estimate the average net profit at more than 18c. per ton, upon which basis the total profit will be about \$200,000 to \$215,000; but, having in mind the high ash-content of this coal, it would perhaps be more prudent to estimate the net profit at 15c. and the total profit at \$165,000 to \$180,000. In making these estimates I have charged to cost of mining a sum sufficient to provide a sinking fund to repay the cost of the necessary plant and improvements. The latter will cost approximately ———— thousand dollars, based upon a capacity of 350 to 400 tons per day, which will be the average output if the property is to be exhausted in 10 years. Basing my estimates of value solely upon this one vein which underlies the property, and disregarding the present market price, which may be purely speculative, of similar property in the same neighborhood, I should appraise the present money value of this property at about \$200 per acre, or say \$32,000 for the 160 acres.”

Doubtless ‘Smith’ would not make an appraisal upon such meagre statement of fact. He would require a determination of the phosphorus in the coke, and of the sulphur in the coal and coke, and might require data as to the dip, water, gas, and other things, with all of which Mr. Finlay will doubtless agree. The writer merely desires to emphasize the necessity for careful revision of articles written by engineers for publication in technical journals. If such articles were read solely by engineers, a certain looseness in writing might be permissible, but as they are doubtless read by thousands of non-technical readers, it is most important that they be couched in language that will not be misconstrued or misunderstood.

H. M. CHANCE.

Philadelphia, January 19.

[Mr. Chance has accentuated the eternal truth that two heads are better than one. Mr. Finlay gave an illustration, and it illustrated his point: Mr. Chance has given an example which we may call exemplary! One supplements the other nicely, but it must be remembered that illustrations are never exact, either in explication of a principle or in erection of a parallel. They share the inherent defect of metaphor. But they enlarge the view and throw light upon a conclusion that else might be obscured in the heaviness of plain argument. We do not think that revision of articles should extend to these details. The personality of the author is worth something: his fallibility is as instructive a warning as the editor’s—and as useful. It is not infallibility that keeps the world lively with opposition. That would place a period, and call for adjournment *sine die*.—EDITOR.]

Coating Cyanide Vats.

The Editor:

Sir—I have heard of a preparation made of tar, rosin, and beeswax for coating cyanide vats, but do not know the proportion of each ingredient. This

mixture is to be made thin, I understand, and applied hot. First a coat is applied to the boards; then a 6-in. strip of 8-oz. duck is spread over, tacked down, and thoroughly painted on top. It is said to act like glue. Can you give any further points regarding such a lining.

R. H. FRASER.

Price of Silver.

The Editor:

Sir—Lately the price of silver has been a grave question to those interested in the production of that metal. During the past year the charge of silver mine operations has formed a part of my work, and with the end in view of obtaining a basis of judgment of what might be depended upon in the way of a possible average price of the metal during operations for the next ten years, I worked out the following data of averages for the 11 years from 1897 to 1907, inclusive. This may be of interest to others. It will be noted that, without exception, the average for the second half of each year is lower than the average for the first half. From the tendency of the price now, after the recent depression, history seems again to be repeating itself.

	First Half-year. Cents.	Second Half-year. Cents.	Difference. Cents.
1897	64.75	51.48	13.27
1898	61.46	54.23	7.23
1899	62.68	58.46	4.22
1900	65.57	58.58	6.99
1901	64.18	54.08	10.10
1902	56.69	47.00	9.69
1903	61.89	47.00	14.89
1904	62.00	53.00	9.00
1905	65.84	55.18	10.66
1906	71.75	62.62	9.13
1907	70.12	52.13	17.99
			Cents.
Average price for the first half of the 11 years..	64.26

ERNEST A. HAGGOTT.

Los Angeles, January 8.

California State Mining Bureau.

The Editor:

Sir—The comments on the California State Mining Bureau appearing in the editorial columns of your journal during the past year have been read with great interest by many of those who have the good of that institution, and the mining industry of this State, at heart.

As your correspondent was the first person to call the attention of the public to the deplorable condition of the Mining Bureau, and cannot believe that this condition will ever be materially changed through the instrumentality of the California Miners’ Association, but must be brought about by other means, the following statement is submitted to the readers of your paper in the hope that it may help to point out the way to the removal of a condition which is a disgrace to one of the greatest mining States in our Union.

Some years ago your correspondent was asked by the present State Mineralogist to take the position of Curator of the Mining Bureau museum and Secretary of the board of trustees. This position was accepted upon the understanding that all the efforts of the Bureau should be directed toward doing the best technical work of which the funds available would allow. After being connected with the Bureau for nearly a year, during which time it developed that political influence, and not the good of the mining interests of the State, was to determine the selection of the Bureau employees, and the expenditure of the funds provided for fostering the mineral industries of the State, your correspondent found himself in a position in which his self-respect and regard for his professional reputation would not allow him to remain. He therefore resigned.

Some time later, through an interview given to the *San Francisco Chronicle*, the attention of the public was directed to the deplorable condition of the Mining Bureau. In that interview attention was called to the fact that the State Mineralogist was filling important positions, which required men of good technical training and experience, with political hangers-on, and his own relatives, who were in no way fitted for the work they were supposed to perform; that the Bureau library was uncatalogued and so ill arranged as to be of little service to those who wished to make use of it, and that no effort was being made to improve its condition; that in the preparation of the bulletin on the 'Copper Resources of California', no part of the work of authorship was performed by the State Mineralogist, and yet he had brought it out as 'The Copper Resources of California,' "by Lewis E. Aubury, State Mineralogist," and that its pages contained no recognition of the work of some of those who had contributed the portions of the highest value; that the bulletin on the 'Saline Deposits of California' was unreliable as a source of information, that it was written by an employee of a corporation floating a company to exploit certain alleged nitre deposits in southern California, and was devoted largely to a description of the company's holdings, and so forth.

The day this interview was published in the *Chronicle* your correspondent was approached at the opening session of the annual meeting of the California State Miners' Association by a past president of that association, who was then president of the board of trustees of the Mining Bureau, and he demanded of him: "What do you mean by that interview in the *Chronicle*?" and in the conversation following he made this remark: "Before we get through with you, you will be mighty sorry you started this thing." He later returned, saying that there would be a meeting of the board of trustees of the State Mining Bureau that noon in which the whole matter would be gone into thoroughly. Your correspondent accepted the cordial invitation given him to be present and at the appointed hour repaired to the meeting place with the documentary evidence of the case, having taken the precaution to have a private stenographer accompany him in order that he might have a record of the proceedings of the

meeting, and might not be done the injustice of having anything he might say misquoted. The president of the board objected to the presence of the stenographer, although he had invited a reporter to be present whose report of the meeting he knew would be satisfactory to the forces that dominate our politics. During the discussion of this matter one of the trustees aptly remarked that it was much easier to start an investigation than to stop one after it was started. The upshot of the matter was that the board adopted a resolution to the effect that they would pay no attention to the charges that had been made and adjourned without looking into the merits of the case at all.

A day or two later the State Miners' Association adopted a resolution, as was their annual custom, endorsing the State Mineralogist and approving of the administration of his office.

The criticisms of the Mining Bureau which have appeared in the editorial columns of the *MINING AND SCIENTIFIC PRESS* have been mild and conservative in comparison with what the condition of the Bureau would justify. Since the attention of the public was first directed to the condition of the Bureau matters have gone from bad to worse; the efforts of the State Mineralogist have been chiefly directed to aiding the Southern Pacific to fight the Western Pacific; the foremost authority on mining statistics on the Coast has been discharged to make place for a newspaper reporter who has won favor by his frequent laudatory references to the great work of Lewis E. Aubury; the same spirit that prompted the attempt to steal the honor of writing the bulletin on the 'Copper Resources of California,' and which, in describing the ancient lakes of the desert region of southern California, inspired the author of the bulletin on 'Saline Deposits' to name the largest and most important one Lake Aubury, and a lesser one Lake Le Conte, has placed the name of Lewis E. Aubury in every conspicuous place possible, even going so far as to have new labels made for all of the specimens in the museum, collected during the whole life of the institution, so that each label might bear the name of "Lewis E. Aubury, State Mineralogist." It is no wonder that one after another of the prominent mining men of this State who have accepted an appointment as trustee of the State Mining Bureau have resigned after they have become acquainted with the conditions at the Bureau, and have found that the forces dominant in our politics have so organized matters that the trustees can do nothing to rectify the conditions.

The present State Mineralogist is well along in his second term of office and his maladministration has long been a matter of public scandal. Where, during all these years, has the State Miners' Association been, that it has not taken this matter up? The California State Miners' Association died a natural death when the real miners of the State wearied of supporting an organization used solely by certain of its officers as a means of fostering their political ambitions. May its ashes rest in peace! That it may ever be resurrected to put the Mining Bureau on a

worthy basis will not be held as a reasonable hope by those who know the inside history of its last years.

To your correspondent, who has given this subject much earnest thought, there appears to be but one way of removing the Bureau from politics and making it of real service to the mineral industries of the State. In a number of States the work of a geological survey is carried on under the direction of a member of the faculty of the State University. The president of the University of California and the faculty of the mining and geological departments of that institution deserve and enjoy the confidence of the people of the whole State. If the present organization of the Mining Bureau were abolished by law and the collections, library, apparatus, and equipment of the Bureau were put in the care of the authorities of the State University, with the understanding that the Bureau, museum, and library should be maintained in San Francisco for the benefit of the public, we could be certain that the force necessary to carry on this work would be made up of the best men available, and that the funds devoted to the work would ensure the greatest possible results.

The exact figures are not at hand, but if your correspondent's memory is to be relied upon, the State has during the life of the Mining Bureau placed nearly half a million dollars into the work carried on by that institution. When we consider what that amount of money could have accomplished if it had been used to the best advantage, we must realize that a change should be made at once, so as to enable the State to derive all possible benefit from future appropriations devoted to this work.

JAMES M. HYDE.

Paradise, California, January 21.

Amalgamation Methods.

The Editor:

Sir—In your issue of December 12 under the above caption, Mr. H. W. MacFarren remarks as follows: "Patent amalgamators to follow plates may be of advantage in some cases, but usually not, as it is the amalgamator's business to see that there is nothing left that can be caught by amalgamation, consequently they should only be put in on trial." In the majority of the mills of the country where the ore will amalgamate there are particles of gold that cannot possibly be caught on the ordinary plates. If Mr. MacFarren is ignorant of that fact, I would suggest that he experiment a little with patent amalgamators and find out for himself. In a mill at Black Hawk, Colorado, I made a 3½-day test below the plates with my amalgamator on ore averaging \$3 per ton. In that test the millman saved 2 oz. 9½ dwt. In the Pierce machine, below the plates and quicksilver traps, I caught 2 oz. 9 dwt. On another test in the same mill, on ore running considerably higher, the saving was in about the same proportion as the first test. In each test the millman or amalgamator claimed I had 'salted' my machine, as he had been in that district for 32 years and "knew" that he was not losing that amount of gold. The

"patent amalgamator," as Mr. MacFarren would term it, told the story.

Robeson & Carter, lessees of the Smuggler Union mill, at Telluride, Colorado, saved over \$66,000 in 11 months below the plates and quicksilver traps; the Pierce machines paid for themselves over 30 times, and in 23 months saved \$106,580. After the Smuggler people had made such a great saving the Tom-boy ordered fourteen 25-ton sets for their mill.

These machines are doing good work below the plates and traps in other parts of the country, and in places the millmen are installing them in place of plates. Mr. MacFarren seems to be of the opinion that no improvement has been made or can be made over the ordinary plate. He also seems to think that whatever is new is wrong, and that experiment means disaster. When Wifley first introduced his concentrating table on the market the wise ones said: "It can't be made to work." But it did work. When I tried to introduce the Pierce amalgamator in certain mills I was met with the rebuff: "It's no use, we are not losing any gold. I have been here for 32 years, and I know. It's simply time and money wasted experimenting with these new fangled amalgamators." But in the face of such opposition these machines are taking the place of plates.

LUCIUS S. PIERCE.

Denver, December 19.

Power in Stamp-Milling.

The Editor:

Sir—On my return to San Francisco, I noticed an article in your issue of December 5, 1908, entitled 'Stamp-Mill Practice on the Mother Lode', by Alex Chalmers. Mr. Chalmers stated at length the many interesting features of the new mill, without making specific comparison with the old mill. The power consumption of the new mill, however, as stated by Mr. Chalmers, cannot be correct: "The 20 stamps, 12 Frue vanners, 36 ft. of 4-in. mill line-shafting, and 34 ft. of 2-in. concentrator counter-shafting consume 40 horse-power." "The stamps weigh about 1000 lb. each, and are given a drop of 7 in., at a speed of 106 drops per minute." Under these conditions the new mill consumes:

$$\text{Horse-power} = \frac{\text{weight of stamp} \times \text{drop in ft.} \times \text{drops per min.}}{33,000} \\ = \frac{1000 \text{ lb.} \times 7/12 \text{ ft.} \times 106}{33,000} = 1.8735; 1.8735 \times 20 = 37.47,$$

the theoretical horse-power.

By dynamometer measurements Von Reytt obtained a ratio of theoretical horse-power used in overcoming gravity to actual power used in overcoming gravity, plus friction, of 1:1.127. Henry Louis computed this value theoretically at 1:1.202. Taking Von Reytt's figure, the actual horse-power to operate the 20 stamps run under the most perfect conditions would consume 42¼ hp. The 12 Frue vanners, line-shafting, and concentrator counter-shafting would easily consume 10 hp. more, so that the 50-hp. motor very likely is working with a slight overload.

I would be interested to know in what details the new mill varies from the old one, so as to account for the great improvement in the work as described.

San Francisco, January 25.

H. HAAS.

GOLD MINING IN COLOMBIA.

Written for the MINING AND SCIENTIFIC PRESS
By F. LYNWOOD GARRISON.

The valleys of the Cauca river and its tributaries are the most important part of the Magdalena river system, which constitutes a network of streams comparable in its lower reaches to the Mississippi, but inferior to our great North American river in volume and length. From its source near Popayán in the great mountains of the Central Cordillera to the town of Cáceres, a distance of about 350 miles, the Cauca river is essentially a large rapid mountain stream. Below Cáceres the valley widens rapidly, the current slackens, and the alluvial gravels gradually disappear as the mountains that parallel its banks sink into the great silt plain built up by the Magdalena river. Both the Cauca and the Magdalena carry an enormous amount of silt, in fact, with the exception of the Colorado river, I have never seen anything to exceed it. Rising in the vicinity of the Purace volcano (16,000 ft. high), the upper course of the Cauca river drains a large area of volcanic rocks, and its waters are said to be so acid that no fish can live in them for many miles from its source. This has given rise to its local name of Rio Vinagre. Some distance below the ancient town of Popayán the river enters a broad valley and becomes a quiet but turbid navigable stream. Soon after passing Cali the western mountains crowd down to the river, and just north of the town of Cartago the valley closes in and the river begins a series of rapids that become more violent as it plunges into gorges so steep and rugged that it is said no footpath can traverse them. For 60 miles above the town of Antioquia there is a stretch of slack-water which is navigable, and then the rapids re-commence and render the river impassable for steamers, at least as far as Valdivia and usually to Cáceres. These gorges and rapids consequently divide the river into two navigable portions which have no commercial relation with each other, the lower one being vastly the more favored, as it has direct and easy communication with the seaboard by the navigable waters of the Cauca river itself and the Magdalena. The upper Cauca river, however, is completely shut off except by way of the railroad connection from Cali to Buenaventura harbor, on the Pacific coast.

Before proceeding further it would seem proper to discuss the geological conditions of this exceedingly interesting part of the world. In order to do this it will be necessary to build up our sketch in a synthetic manner from the fragmentary and not always reliable statements of the few geologists or pseudo-geologists who have visited the country. The most southerly mountains of Colombia are a confused mass which extends into Ecuador and includes the great volcanoes Sangay and Cotopaxi. None of the volcanoes in Colombia are of great elevation, but several are from 14,000 to 16,000 ft. high. The three ranges which spring from this central cluster of mountains are known in Colombia as the Western, Central, and Eastern Cordilleras. As the Cauca valley and its tributaries, the Nechi and Porce, lie be-

tween the Western and Central Cordillera, we need not concern ourselves at present with the Eastern. The axis of the Western Cordillera appears to be chiefly composed of eruptive rocks having an andesitic or porphyritic character. This backbone is flanked on both sides by metamorphic rocks of a distinctly pre-Cambrian type. Upon the gneisses, granites, and schists of this formation are sedimentary rocks of the Triassic or Jurassic, and possibly in the district we now are considering, some Cretaceous. The Central Cordillera begins at the Ecuador frontier with a group or range of recent volcanoes, including Huila, 18,000 ft.; Tolima, 18,400; Ruiz, 17,400; Santa Isabel, 16,700, and the Mesa de Herveo, 18,300, the last being the remains of a still greater cone, the top of which was probably blown off, leaving a vast crater with a level outline, giving at a dis-

Map of Colombia.

tance the appearance of a flat table-land. The summits of Ruiz, Herveo, and Santa Isabel are collectively known as the Páramo de Ruiz. As the central range progresses northward into Antioquia, it gains in breadth and loses in height, the volcanic rocks being replaced by metamorphic formations of pre-Cambrian character, similar to those of the Western Cordillera. J. C. F. Randolph* states that evidence is not lacking that in many points of the Central Cordillera the eruptive rocks have broken through the schists and form the backbone of the range. The schists coincide in strike with that of the range, and dip east. This formation in turn is overlaid by Triassic sandstone, and at places thin patches of Jurassic limestone containing characteristic fossils; the Triassic sedimentaries have been much broken and distorted, probably at the time of the upheaval of the Central Cordillera, and are frequently seamed with dikes of andesitic and other magmatic rocks. Randolph considers that these upheavals took place either at the end of the Triassic or the beginning of the Jurassic, and that subsequent erosion in Quater-

*Trans. A. I. M. E., vol. XLIII, page 209.

nary time produced the gold-bearing alluvials. This competent observer refers more particularly to the district of Tolima, with which he was personally familiar, but he states that, according to the consensus of opinion of other observers, similar conditions are found north in the State of Antioquia, as well as in the Western Cordillera. Judging from my own limited observations in Antioquia, I believe these deductions are correct. I found what Randolph calls Archean rocks, but what I would prefer to consider pre-Cambrian, abundantly exposed in the Cauca valley, especially in the section between Cáceres on the north and Valdivia on the south. The greatest elevation I personally obtained above the Cauca valley was about 2500 ft., at Raudál, in the Central Cordillera. The mountain tops at this place have been cleared for several hundred acres, to afford grazing, hence it was comparatively easy to make observations upon the underlying rocks, and I found everywhere nothing but these metamorphic schists and gneisses, seamed and laced by innumerable quartz veins carrying a small quantity of gold. Some of these veins are from 20 to 25 ft. thick, and may be traced for miles. I had been told that they were quite rich at places, but my own sampling did not confirm this statement. I found them lean, as is usually the case with massive dull white quartz veins. I noted a few instances of dikes cutting the schists, but as a rule they were small, and apparently not numerous. It must be remembered, however, that the difficulties in making geological observations on mountain sides clothed with tropical jungle are tremendous. The district of which I speak is extremely wild; there are no roads, few trails, and in the rainy season these are horrible beyond description; moreover, there are few inhabitants. I know of nothing more exhausting than climbing up and down these jungle-clad mountains in the wet season. The moisture-laden air admits of little or no evaporation from the skin, and throws a strain upon heart and lungs not to be long endured with impunity by most men. These difficulties, of course, lessen with the elevation, but it was not my luck to be much in higher altitudes above the moisture-laden atmosphere of the river valleys. Randolph, in referring to the quartz veins in the schists of Tolima, says, "These veins have a general tendency to wedge out and reappear in sympathy with the mobile curves of the schists. No vein cutting the formation has yet been found in Tolima. As a rule these veins in the schists are thin and of little value."* It might be remarked in this connection that generally throughout South America, the coast Cordillera (which in Colombia splits up into the Western and Central ranges) is formed to a considerable extent of rocks having an Archean aspect, such as gneisses, mica schists, etc., associated with old eruptive rocks, and deposits of sandstones and shales, usually devoid of fossils. According to Suess† it is by no means certain that these rocks are actually Archean. Darwin appears to have entertained similar doubts.

The problem seems now by no means nearer solution than 75 years ago, and probably cannot be cleared up until South American, or more particularly Andean, geology has been more thoroughly and carefully studied. Personally I prefer to class these rocks as pre-Cambrian, although it seems one can never be sure as to what particular age metamorphic rocks may belong. I have seen metamorphosed sedimentary rocks so like metamorphic eruptives that it was almost impossible at first sight to distinguish between them, yet one was certainly Archean and the other Tertiary. I can never feel sure when I call a rock Archean that it is not something else. In view of the important relation that this class of rocks bears to some of the greatest gold deposits in the world, especially the alluvials, its proper determination is a matter of much more than mere scientific interest.

The Cauca valley, at least that portion between Valdivia and Cáceres, is probably a synclinal trough, the Western Cordillera forming one and the Central the other side or arch. The Western range is much the higher of the two, and it is probable that the eruptive rocks of its core break through at the summit or crown, leaving the metamorphic rocks on the flanks. These metamorphic schists and gneisses constitute the foothills that extend from the Cauca river to the main range, and it is probable that in the innumerable gold-bearing quartz veins, which in places constitute a considerable proportion of their bulk, is to be found the source of much of the gold in the alluvials. In the section between Valdivia and Cáceres the Central Cordillera is much lower than the Western, and seemingly the eruptive or magmatic rocks have not broken through the apex of the range. The rocks of the Central range are apparently similar in this respect, and have doubtless contributed a large quota of gold to the river gravels, but this proportion is probably less than that derived from the Western range, as there are fewer small tributary streams or feeders flowing down from the mountains on the eastern side of the river.

The bulk of the gravels in the bed of the Cauca river appear to be composed of porphyritic and andesitic rocks; granite and gneiss are common, but as might be expected from their softer nature, schists are rather rare. We may infer from this that most of the pebbles and boulders come from the Western range, and that the proportion of metamorphic rock in the river gravels is small, except near the mouths of the large tributary streams. This fact is of practical importance, since the gravels where un-enriched by the wash of the side streams, are probably too lean to pay to dredge, whereas at the mouths of these large streams, such as the Taraza, and at some distance below the point of confluence, the gravels show evidences of richness. The amount of erosion necessary to have produced the gravels of the Cauca river valley must have been enormous, as our drill-holes showed a thickness of more than 40 ft. in the very bed of the river; and the benches or *cerros* on the banks often rise straight up 60 to 75 ft. above bed-rock. This condition is well illustrated at the Icobo,

*Ibid, page 211.

†'Face of the Earth', Vol. I, page 538.

hydraulic property about 10 miles below Valdivia. None of the gravels that we saw in the district were cemented, and below the Angostura gorge, that is, near Cáceres, there are no evidences of large boulders. The gravels composing the old Quaternary benches back from the rivers are often much decomposed, containing some clay, but judging from our observations, there is usually not enough present to seriously interfere with hydraulic or dredging operations; at least I saw no distinct beds or layers of clay intermixed with the gravel. Wherever there are decomposing feldspathic rocks the presence of some clay is inevitable, but in this case it does not appear to be segregated or disseminated in sufficient quantity to cause much trouble.

A notable characteristic of the gravels in the Cauca river bed is the presence in them of large amounts of pyrite, especially in the eruptive rocks. A condi-

of the gold in alluvials is derived from the eruptive rocks is impossible to conjecture. It seems probable, however, that most of it comes from the veins in the schists, for they often possess visible gold, whereas it is uncommon in the eruptives. The gold in the

Testing Gravel With Empire Drill.

tion similar to this has been noted by Levat, in the diorite gold-bearing gravels of French Guiana.* In this instance as much as 5.2% FeS_2 was found in some of the diorite, which on assaying showed from 15c. to \$1.24 gold per ton. It might be observed in this connection that in Guiana the decomposition of these diorites has given rise to accumulations of clay in the gravel, causing a serious drawback to their successful treatment for recovery of the gold, moreover, these deposits as a rule are said to be shallow, and situated in unhealthy districts. On the contrary, the Cauca river gravels are almost always thick, uncemented, and contain relatively little clay. In French Guiana, as in Colombia, the source of the gold appears to be chiefly in the numerous quartz veins intercalated with the crystalline schists of the metamorphic rocks. Levat observes† that these quartz veins are usually lean, except in the vicinity of the accompanying dioritic rocks. Just what proportion

Street in Candeva.

gravels of the Cauca river bed does not differ much in appearance and purity at various places in the district under consideration, but in the benches along the sides of the river are quite appreciable variations, in fact the storekeepers of the little mining towns of

Hydraulic Mining in Icolo.

Cáceres and Candeva claim, and I think with truth, that they can detect with a glance from what particular locality or property any lot of gold dust has been obtained. These variations are chiefly due to the color, the purer the gold, the deeper its yellow

appearance; then again, some of the gold is rusty, or coated with oxide of iron, and indicates that it came from old bench gravels in which much rock-decomposition has taken place, the leaching, oxidizing action being responsible for the deposition of ferric oxide on the particles of gold. Similar facts are of course familiar to most placer miners, but it seems proper to call attention to the matter in this connection, as in this way we may be able to account, in some measure at least, for the so-called rustiness or reddish color of the gold and the apparently unexplainable difficulties often encountered in amalgamating. The gold derived from the decomposition of pyrite in the eruptive rocks must usually be set free in an exceedingly finely divided condition, and the question arises, does it in this form contribute any increment to the recoverable gold in the gravel. In other words, is it possible owing to its extremely minute condition, to save some of it along with the coarser particles? It seems probable that little, if any, of this gold can be saved, unless it be dissolved by the river water and re-precipitated upon the larger gold particles in the gravel. The solubility of gold and its re-precipitation from solution in alluvials is a question upon which there is much difference of opinion; it cannot be discussed in this article, and may be dismissed with the query, how does gold become purer and purer as it travels away from its source, unless the silver it originally contained is removed by solution? There can be no doubt as to this fact, for it has been noted over and over again in different parts of the world, but how this natural refining operation takes place is not so clear.

The quantity of gold in the Cauca river alluvials is, as in other similar deposits throughout the world, exceedingly variable. The rich streaks of the bench gravels along the river side will often run as high as \$1 per cubic yard; close to the water's edge where eddies have deposited much river wash, small areas are sometimes found of extraordinary richness—\$4 or \$5 per cubic yard. Seldom does one fail to find at least some small particles or 'colors' of gold in a batea (pan) full of gravel. The existence of the gold in the gravel is almost universal, but of course erratic in quantity if not in quality.

The metamorphic series of rocks are overlaid by sedimentary deposits, said to be Triassic or Jurassic in the States of Tolima and Cauca, and probably Cretaceous in Antioquia. It seems likely that the identification of these formations has been in the main correct as far as Tolima and the southwestern portion of Colombia are concerned, but whether the sedimentaries of the Cauca valley in Antioquia are Triassic or Cretaceous, it is impossible at present to say, because no fossils have yet been found in them, nor indeed, as far as I know, have these rocks been studied by any competent geologist. Between Valdivia and the Angostura gorge the sedimentaries appear in only a few spots, increasing in frequency northward. They are well exposed above the falls of the Puqui creek, a short distance north of the town of Candeva, and they can also be seen in small quantity at the hydraulic workings of Icobo on the west bank of the Cauca. The Angostura gorge ap-

pears to be entirely of metamorphic rocks, which outcrop as far down the river as the Apavi ranch; below this point the rocks along the line of the river are all sedimentary, consisting of sandstones, grits, clays, and fine pebble conglomerates.

At several places in the vicinity of the town of Cáceres, notably on the Taraza river at a place called Cacagual, coal seams are found in the sedimentary rocks, which at this place outcrop along the side of the river. The seams here dip north 10° east, the upper one of the series being about 8 in. thick. There are several lower veins, ranging from 18 to 30 in., and finally a large seam, the thickness of which I could not accurately determine, but it is probably 4 or 5 ft. This seam comes to the surface back in the jungle, and is not shown in the illustration. It is evident, from even this cursory examination, that the coal deposits cover a large area and include some workable seams sufficiently accessible to be of commercial importance. The character of the coal is unusual; it is compact, glossy, and does not soil the fingers, resembling cannel coal. When powdered, the coal shows no brownish tint, and it possesses a distinctly laminated structure. When held in the hand it can be lighted from a match and burns with a glow like punk, but not with the long flame of cannel coal. The following analyses show the composition of the coal found on the Taraza river:

	I. Per cent.	II. Per cent.
Moisture	13.60	15.36
Volatile carbon	38.10	47.41
Fixed carbon	44.40	32.67
Ash	3.80	4.56
Sulphur	0.547

It is evident from this analysis that it is a highly gaseous coal of unusual purity, containing a large amount of moisture. I am disposed to think that coals from moist tropical countries may be peculiar in this respect, although a high proportion of moisture is certainly not unusual in North American coals.

The area of workable coal deposits in Colombia is apparently large, but as yet there are practically no coal mining enterprises in the country. Large deposits are reported at Cali, on the upper Cauca river, some 200 miles north of Cáceres. In the State of Cundinamarca, near the capital city, Bogotá, are some large deposits, and in the Sierra Nevada mountain complex on the Rancheria river near Rio Hache on the Caribbean coast are other extensive coal deposits. Many years ago the famous Dr. John Percy, of the Royal School of Mines in London, analyzed a lot of coals from Colombia, and published the results in his book on fuel, with the following notes:

	I. Per cent.	II. Per cent.
Carbon	76.45 — 81.86	56.66 — 72.65
Hydrogen	4.88 — 5.22	4.08 — 5.23
Oxygen and nitrogen ..	12.06 — 12.92	17.25 — 22.12
Sulphur	0.25 —	0.30 —
Ash	1.25 —	2.63 —
Water	5.11 —	19.08 —

"No. I is a non-coking coal, rich in oxygen. It is black, compact, firm, but not bright and scarcely soils the fingers, no trace of iron pyrites can be seen

in it with the naked eye; it produces a long flame and may be regarded as a valuable fuel for raising steam, smelting in reverberatory furnaces, etc. It yields a slightly coherent coke. Color of the ash, pale gray with pinkish tinge. Calorific power in Thompson's calorimeter, 13.75."

"No. II is evidently lignite, properly so called, as far as composition is concerned. It is black, and so tender as to be incapable of transport or storage without crumbling. Thompson's calorimeter gave 9.90."*

These coals, I believe, came from the Rio Hache district, or else from some beds near the gulf of Uraba (Darién). The coal of the Cáceres district is certainly not lignite, and possesses the unique distinction of being overlaid by thick rich beds of

Gold-Gravel Overlying Coal-Beds.

auriferous gravels, hence a dredge or steam shovel operating in this district might get its fuel and gold from the same tract of ground.

Colombia is the least known, and the least developed, of the South American republics, yet of all of them it is the most accessible from the United States, and by virtue of the great Magdalena river and its navigable tributaries it has a channel of entry, and opportunities for cheap transportation to hundreds of miles of its interior, not possessed by any of the Pacific coast republics of South America, Central America, or even Mexico. There is the best evidence that the mineral resources of Colombia are great, especially as to gold and coal. Unstable government, and the rugged topography of its southern districts, have been great obstacles to its progress and development. The climate of the Magdalena delta is unhealthy, but the upper river and the Cauca valley are salubrious although hot, while every variety of climate, from temperate to frigid, may be

found in the mountain districts of the south and the high plateau of Bogotá. Judging from what I personally saw of this great country—and it was very

Gold 'Colors' in Batea.

little—I firmly believe its undeveloped resources are extraordinary. Possibly I have seen only a favored spot, as the lower Cauca valley undoubtedly is, but while this may be true, it seems likely that there are

Native Pump, Valdivia.

other places with equal or superior advantages, although as regards transportation to a mountainous mining district, this would hardly be possible, for there already exists direct steamboat communication between the coast and the town of Cáceres, in the heart of the district under discussion. It is not safe for one, even though he be an experienced traveler like myself, to spend but a few months in a foreign country, and then draw definite and comprehensive conclusions regarding it; yet by conversation and close study it is sometimes possible to obtain fairly accu-

*Percy's 'Fuel,' page 339.

rate ideas of even so large and sparsely inhabited a country as Colombia, its people, and, as far as known, its resources. Hence, when I venture the prediction that within the next decade we will hear of Colombia, the Panama Canal, and the real Eldorado, bracketed in one and the same thought, I may perhaps not be going too far.

A number of mining schemes and enterprises have been exploited in Colombia, many of which have been dismal failures; dredging contraptions that could not possibly work or pay in California have been thought good enough for Colombia; men absolutely without experience in any kind of mining have been placed in charge of operations in this country, a place where honesty, prudence, experience, and a resourceful character are prime requisites in a successful manager. Business men otherwise sane put their money into these crazy schemes, and expect miracles to happen, and when inevitable and deserved failure results they condemn the country, its people, climate, and government, and end by saying, "it's too far away from home," which a glance at the map shows to be absurd, for the town of Cáceres, far in the interior of Colombia, is about the same distance from New York as is Salt Lake City. One or even a dozen swallows do not make a summer, and the score or more of crazy mining enterprises that have failed in Colombia should not condemn this great, rich country, or prevent its development by Americans with brains and money.

No better substantiation of my good opinion of Colombia as a future gold-mining country could be adduced than the statistics of its gold production since the Spanish conquest. These estimates are based chiefly on the researches of Vicente Restrepo, a painstaking Colombian gentleman, who published in 1886 a book entitled, 'A Study of the Gold and Silver Mines of Colombia'. The English translation of this work was published by C. W. Fisher in New York in 1886. I have not been able to obtain the English version, so I quote from the last edition of the original Spanish.* According to this authority the total production of gold and silver up to 1886 was \$672,000,000, of which \$639,000,000 was gold and \$33,000,000 silver. Since 1886 the total annual gold production of Colombia may be estimated at about \$2,500,000, at which rate the total yield down to the end of 1908 would be \$694,000,000 in gold alone. Of this great total it is estimated that a little over one-half was produced by the Department of Antioquia, and nearly as much by the State of Cauca, the proportion, of course, being the same for each annual yield. Restrepo distributes the total gold production during the historical period as follows:

	Gold.	Silver.
16th Century	\$ 53,000,000	\$ 6,500,000
17th Century	173,000,000	9,000,000
18th Century	205,000,000	1,500,000
19th Century (to 1886) ..	208,000,000	16,000,000
	639,000,000	33,000,000

Estimates by different authorities of the total gold

production in Colombia show considerable difference. De Launay* places it, down to 1902, at \$910,000,000. Granger believes it to have been about \$1,000,000,000.† Other writers have placed it at about \$750,000,000.‡ Personally I am disposed to take Restrepo's figures as the most reliable, at any rate it is likely the gold production of Colombia has exceeded that of any other South American country, including Brazil.

It is of interest at this point to compare these figures with the total yield of the chief gold producing countries of the world. The production of California since 1848 has been \$1,400,000,000; of Australia, from the year 1851, including Victoria (\$1,300,000,000) and West Australia (\$280,000,000) is \$2,710,000,000. Russia and Siberia have produced \$1,300,000,000, South Africa about \$1,000,000,000, and some authorities put the yield of Brazil at \$780,000,000, but this is probably excessive. Of late years the production of California, Australia, and Russia show a steady decline, while that of Alaska and South Africa display a great increase. When we consider that few mines in Colombia are provided with modern equipment and that nearly all of this vast yield of gold has been produced from alluvials by hand-washing with the wooden batea, the result is remarkable. One may therefore be pardoned the extravagant statement that modern mining appliances and equipment, backed by energy, brains, and money, would make Colombia the greatest gold-producing country the world has ever seen. The amount of gold that has been won by the primitive batea must surely be little as compared to what it is possible to produce by modern methods. While there are evidences of old workings almost everywhere in the Valdivia-Cáceres portion of the Cauca valley, the amount of gravel worked is certainly insignificant as compared with the vast area of alluvial deposits to be found there. Moreover, the old workers operated only the rich spots, as do the natives now. The tendency of modern gold mining is to greater and greater economy, and an enormous increase in the amount of material handled. This is especially true in dredging, and we certainly have not yet realized the limits of improvement possible in mechanical and chemical methods of gold recovery. If the business activities of the world are to increase in the same proportion as in the past decade, we must have more and more gold to meet the demands of trade and the consumption in the arts. In the face of a declining production from the older gold mining countries, new fields must be found. In a modern sense, Colombia cannot be considered an old gold producing country, though strictly speaking it is one of the oldest. By that I mean, modern appliances have so changed the aspect of the industry that Colombia is not in the same class as a gold producer with California, Australia, and Alaska. Some ill-informed economists (not mining engineers) gravely tell us that the great improvements in modern mining methods of gold re-

*'Estudio Sobre las Minas de Oro y Plata, de Colombia.' Bogotá (Segunda Edición), 1888, pages 149-159.

*'The World's Gold.' Putnam Sons, N. Y., 1908, page 119.

†'Engineering and Mining Journal', Aug. 4, 1906, page 194.

‡Ibid, May 30, 1908, page 1096.

covery will not only maintain our present gold production in the old districts, but may cause a steady increase. Anyone who has carefully considered the matter and is familiar with gold mining and milling will not believe this, and statistics bear out the assertion. The great bulk of the world's gold production comes from alluvial deposits, and when they are exhausted, and not until then, may we begin to worry. The unique deposits of the Rand in South Africa are in fact alluvials metamorphosed or at least silicified and solidified into beds and seams, commonly but incorrectly called reefs, and subsequent to this hardening they were tilted or inclined at a high angle to the horizontal by deformation of the strata. It is therefore evident that these great and profitable deposits in South Africa belong in the category of alluvials.

ELECTRIC STEEL REFINING.

In the field of steel refining electrometallurgy is now making most striking and most important advances. This has not been an evolution of the steel industry from within, but an invasion of the field from without. Not only were the pioneers of this development electrochemical engineers rather than practical steel men, but in view of the skeptical and reluctant attitude of the existing industrial steel plants, these pioneers were forced to erect their own electrical steel works independent of the existing industry. Thus Héroult installed his own steel plant in connection with his aluminum and ferro-alloy works, Kjellin had his own induction furnace steel plant in Sweden, Stassano erected large works of his own in Turin, and now Girod is building a special steel plant of a size which should surprise any doubting Thomases. There are now in operation or in course of erection 19 Héroult furnaces of an aggregate charge capacity of 63,300 kg., and 5 Héroult furnaces the capacity of which has not yet been definitely decided; 11 Stassano furnaces of an aggregate capacity of 16,900 kg.; 8 Girod furnaces with a capacity of 34,000 kg.; 10 Kjellin induction furnaces with a capacity of 21,500 kg.; and 10 Roebling-Rodenhauer modified induction furnaces with a capacity of 29,200 kg. The above figures include 2 Héroult furnaces in this country, the other 22 being abroad. The furnaces of the other types are all in Europe. There are, however, some small Colby induction furnaces in operation in this country; one, chiefly for demonstrating purposes, at Niagara Falls.

There is evidence now of a change of attitude by the existing steel companies of this country toward the electric furnace. One of the most interesting signs of the time is the testimony given by Charles M. Schwab before the Ways and Means Committee in the tariff hearings, who said: "We have taken another step in advance, which has been developed by the Germans, and that is the electric method of producing steel, which is an advance again over the open-hearth, that I am certain in the next ten years, or probably quicker, depending upon the rapidity of the development, will probably make all open hearths practically useless. These processes

have not been for the purpose of cheapening the product, but of bettering the quality."

The electric steel furnace will not displace the open-hearth or the Bessemer converter. It is considerably cheaper to make steel in two steps in the open-hearth (or in the converter) and refine it in the electric furnace, than to make it in the electric furnace alone in one step. Dr. Héroult's method of operation is to extend the open-hearth process to the point where the steel is dephosphorized to the desired degree; it may then be highly oxidized, but this does not matter, as the steel is to be treated now in the electric furnace. There the steel is de-oxidized (which is possible on account of the reducing atmosphere of the furnace), the sulphur is reduced, and the steel is re-carbonized to the desired degree. The desulphurization accompanies the de-oxidation, and the remarkable success of desulphurization is due to the formation of calcium sulphide, which is a specific electric-furnace re-action. In this way it is possible to get a final steel product in which the sulphur and phosphorus are reduced to any desired degree. An important advantage of the product is its great uniformity and homogeneity, and its freedom from oxides, gases, and slag. This fact will make electric refining highly desirable; even in cases where steel is made from low-phosphorus and low-sulphur pig in the open-hearth. *Electrochemical and Metallurgical Industry.*

Graphite, molybdenite, ilmenite, and hematite are four minerals that, because of their habit of crystallizing in dark shiny flakes, are sometimes mistaken in the field one for another. The first two, by their extreme softness, both soiling the fingers when in sufficient amount, can be immediately distinguished from the latter. Without chemical tests graphite can be told from molybdenite only by its slightly different color and, when of possible determination, by its comparative lightness. Graphite is distinctly iron-gray in color; molybdenite is lead-gray, with a distinctive bluish tinge. Chemically, graphite being pure carbon, the molybdenite, the sulphide of molybdenum, a simple test for sulphur, in the open tube or on charcoal, serves at once as a basis for identification. When ilmenite and hematite in scales cannot be told apart, as in some metamorphic rocks, a chemical test for titanium must be made. The presence of this element indicates the former mineral. This test is made by fusing the powdered substance with soda, dissolving in hydrochloric acid, and boiling with granulated tin. If titanium in more than traces be present, a delicate violet color will be produced.

Beginning with January 1, 1909, the postage on letters to Germany was reduced to 2 cents per ounce, the same as the domestic rate and also the same as the present rate to Great Britain, Canada, and Mexico. The rate, however, only applies when the letters are dispatched by steamers sailing direct from an American to a German port. If they go by way of Great Britain or France, the postage will be charged at the regular postal union rate of 5 cents for the first ounce and 3 cents for each additional ounce.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Stamp-mill dies should be harder and more elastic than the shoes. Resiliency in the die is of as much importance as is the absence of it in the shoe, in order to give high efficiency.

Iridosmine, which is generally associated with platinum, is in fair demand. The price rules slightly lower than platinum, being at the present time about \$18 per ounce, less a refining charge of \$2.

Gold amalgam is soluble in KCy solution. In some experiments made in South Africa, I. Roskelley showed that 111.6 grains of amalgam were reduced to 99.2 grains in 12 days by exposure to a 3% solution of potassium cyanide.

Rolls are overworked when crushing from the average maximum of ore fed to less than one third that average size. Greater economy results from working rolls at proper capacity. Locomotive-tire steel is the best material for roll-shells.

Automatic tailing-samplers usually traverse the stream, taking a split from one side to the other, and back again. This gives fairly accurate results. A better principle, however, is to take the entire stream for some small unit of time. This gives a larger initial sample, which requires to be re-sampled by the same system.

Stamp stems break at the nodal point in the vibratory wave set up within the stem by the jar. The greatest stress is not at the point of greatest amplitude of vibration, but at the nodes, which are just above the boss-head and just below the tappet. The crystallization of the steel in stems by reason of vibration is generally assumed, but has never been conclusively proved.

Manta is a Spanish word which, as used in connection with mining, means a horizontal vein similar to the type colloquially termed a 'blanket deposit'. Many miners in Spanish countries distinguish between veins dipping between 15 and 45°, called *vetas de manta*, and those from 15° to horizontal, called *vetas de sombra*. The term is also applied in Central America to auriferous detritus covering hillsides, and to deposits resulting from enrichment on the surface of a decomposing vein, such as have been termed 'saprolites' in the South Atlantic States.

Relative costs of city coal gas and producer-gas, as fuel for generating steam and for use in melting furnaces, depend on many factors. Where the source of gas is exclusively coal, the question reduces to the magnitude of consumption for steam-generation and for metallurgical purposes. For small units undoubtedly contracts could be made with established gas companies at prices less than the cost of production by individual gas plants. Large consumers would, of course, find producer-gas far cheaper than

retort-gas; moreover, for power-generation the producer-gas can be used direct in gas-engines, eliminating the boiler-plant entirely.

Silicates are classified on the basis of the ratio between the oxygen in the base and acid of which they are composed. The simplest types of silicates accordingly fall within the classifications of sub, mono, bi, tri, and sesqui-silicates, having corresponding ratios of oxygen in base to oxygen in acid of 2 to 1, 1 to 1, 1 to 2, 1 to 3, and 2 to 3. For example, a tri-silicate has the general formula $R_2Si_3O_8$, which corresponds to $2RO \cdot 3SiO_2$. Where the base enters the compound as a sesqui-oxide (R_2O_3) the ratio still holds good, as for example in the tri-silicate $2R_2O_3 \cdot 9SiO_2$. Singulo-silicate is another term for mono-silicate.

Protective alkali needed by a pulp in the cyanide process is determined by making up a number of samples of the ore with cyanide solution to which quantities of lime, varying from 0.1 up to 1%, have been added. These are agitated every 10 minutes, and a sample taken from each bottle every hour, filtered, and the filtrate tested for KCy. This shows approximately the proper quantity of lime to use. Following Julian & Smart, the preliminary test having shown where the saving in KCy is stopped, take 3 samples of the ore of 20 lb. each, mix with lime in proportions equal to, above, and below the indicated quantity, place in filter jars, and run on an amount of 0.2% KCy solution, one third the weight of the ore. Leach the same solution through the pulp twice, and test for KCy. The economical minimum of lime needed for protection is thus ascertained.

A mining claim was located by A, who held possession for six years without performing the annual labor required by law. After his death B located the claim. Has A's estate any right under the circumstances that would invalidate B's location? Assuming that B's location was made peaceably and that the acts of location were regularly performed, and that A's claim did not have the required amount of assessment work done on it up to the time of B's location, and also that A's heirs or legal representatives had not resumed work and were not continuing it with diligence at the time of B's location, it may be said with reasonable certainty that B's location is valid. The death of the owner of a location does not alter the status of the claim in any sense, as far as the necessity of performing assessment work is concerned, and the title to the claim which vests in A's estate has the same character, and is subject to the same conditions, as it was prior to the owner's decease. The owner's death does not obviate nor excuse the necessity for the performance of annual labor, even though his heirs may all be minors or unknown. Up to the time that B makes his location, A's location is still a valid and subsisting one. The mere failure to perform annual labor does not *ipso facto* terminate A's title and cause a forfeiture. The forfeiture takes place only where a new location comes into existence. This has the effect of terminating the title to the older location.

PROTECTION OF INVESTORS.

Herewith follows the remainder of the discussion, the first part of which was published in our last issue. It was a discussion held at the meeting (on December 19) of the Pacific Coast division of the Mining and Metallurgical Society of America.

Albert Burch.—In addition to the items covering operations in the past, a report at the end of a certain period should give as reliably as possible a forecast of the earnings of the mine for the following period, to the time of the next report forthcoming; and, furthermore, in the case of all metals, except gold, the price of the metal on which the estimate of value is made should be specifically stated in the report, so that the investor can deduce for himself how the results will be affected by variations in price.

T. A. Rickard.—May I relate an incident that has reference to what Mr. Burch has said? In 1905, I met a mining engineer, whom most of you know, at a hotel in Mexico City. He had just written a report on a copper mine in Michoacan. He showed me this report and asked me what I thought of it. I found that his estimate of the future profits was based on copper at 13 cents. I said to him: "Why do you do that?" "Well," he said, "that is the average of the last five years." I replied: "That is so, but you are forecasting the next five years, and you know well enough that the expectation among those who are in touch with the copper market is that copper will be more like 17 cents than 13." He said: "Yes, but I wanted to be on the safe side." I said: "No sir, you have no right to put yourself on the safe side. You are here to give honest advice, and if you believe that the price will be 17, you have got to state it at 17, for it is just as much your duty to forecast the price on which your estimate is based as to make an estimate of the tonnage. Your estimate of the tonnage is worthless unless it is tied to an estimate of the price of the metal." He said: "We engineers are not supposed to forecast the price of the metal. All we have to do is to report what we have found."

Charles Butters.—I might make a little remark in that connection. At one time I was doing a large piece of business with the Calumet & Hecla people, relative to treating their accumulated tonnage of tailing and the future ore produced by the Calumet & Hecla mines, and I drew up a statement regarding the profits that would be made from the work. Mr. Livermore, the vice-president of the company, looked it over carefully and saw the price that I had put on copper, on which I based my profit. As the business was to extend somewhere between 25 and 30 years, he and Mr. Agassiz stated that anyone going into the copper business should always be prepared to meet the lowest price that copper had ever seen. He said: "We have seen copper twice at 9 cents"; and added: "If you cannot make a profit at 9 cents, your figures are not sound. We have seen it twice at 9 cents and we are liable to see it again."

S. B. Christy.—That was for a 25-year period.

T. A. Rickard.—What did you say?

Charles Butters.—I thought the point was well taken.

S. B. Christy.—In regard to the point raised by Mr. Rickard: It seems to me that it is difficult to value a mine at a given price and then take the responsibility of its failure to do so by reason of a drop in the price of a metal. It adds a great deal to the engineer's responsibility.

T. A. Rickard.—That is what he is paid for. He is paid to advise honestly in regard to the future; he should give the same advice to his client that employs him as he would to his own brother. An engineer does wrong when he makes an estimate and divides it in two for safety.

W. H. Shockley.—Would it not make a difference whether he made a favorable report or not? If he turned down the property on the basis of the price of 13 cents and it went down, I do not see how it would be hurtful to his principals.

S. B. Christy.—It seems to me that there is nothing further to be said on the first head. We may take up the second, which Mr. Burch has ably opened: "How may mining companies be compelled to give such necessary items of information?" It appears to me that everybody who has touched on this subject so far has actually said that it is impossible to do so by State legislation. I think it would be unwise to even attempt it, unless it could be done by the United States Government.

C. W. Merrill.—I would like to ask Mr. Burch why it would be impossible for it to be so done.

Albert Burch.—The reason is: a dishonest mine management would easily find a way to evade any law that could be framed by any legislature, so as to comply with the letter of the law and yet violate the spirit of it in the matter of giving out mine reports—that is, compulsory mine reports. But a law could be so framed as to provide a penalty for the publication of deliberate falsehoods in connection with mine reports or in connection with mining stock advertisements, such as we see every day in the daily papers. A statute could be framed imposing a penalty for such falsehoods. But to prescribe a form for mine reports that would always contain the truth, I would consider would be impossible if the management were dishonest and wished to avoid that provision of the law.

S. B. Christy.—Would you think it possible to punish a management possessing information obtained in the way you have described and withholding it from the public? It could easily be proved that they had that information.

T. A. Rickard.—Would you call it a falsehood not to give the public information obtained by drilling holes in the way you described?

Albert Burch.—All they say is that the face of the drift is not in ore.

S. B. Christy.—Would not the intent to deceive be obvious?

Albert Burch.—It would not suffice to convict a man.

S. B. Christy.—Could you not prove that they withheld information that affected the value of the stock?

T. A. Rickard.—They would not state that they were putting in drill-holes.

Charles Butters.—Those drill-holes would be put in

during the night by one man when no one else was around.

M. L. Requa.—If the State cannot pass a law that will cover the situation, the Federal Government cannot, unless the mining company is engaged in interstate business. You might pass a national law that would cover the mining companies engaged in interstate commerce, such as the shipment of copper; but if you take the mines of the State of California that produce gold and ship it to the Mint or sell it in the open market here, there is no national law that you could pass that would reach those corporations.

S. B. Christy.—Could it not be done through the post-office department? For example, pass a law prohibiting the sending through the United States mails of any reports that fail to comply with specific requirements, and making it a penitentiary offense to do so. All statements circulated for the purpose of selling stock are distributed either by means of the newspapers or in dodgers that are sent around through the United States mails; such a law would reach about 90% of them.

Albert Burch.—That is true as to advertisements for the sale of stock, but it does not cover mine reports. A mine report can be made so as to be absolutely truthful and yet not tell anything about the mine.

T. A. Rickard.—Would it not be a good thing to make the mining companies incorporate under the laws of the State in which they did business?

M. L. Requa.—As far as California is concerned, you have to conform to the laws of California if you do business here.

Whitman Symmes.—Our law reads: "Every corporation formed for the purpose of mining, or conducting mining in California, whether such corporation be formed and organized under the laws of the State of California, or of any other State, Territory, or foreign country." I think that our laws do good; for instance, the Comstock companies are compelled to say, among other things, how much money they have on hand, and what they owe. I know of one case where a failure to so report was a cause of some loss. Mr. Clarence Mackay put some money into the Yellow Jacket mine, and on the strength of that some other people bought Yellow Jacket stock, not knowing that the Yellow Jacket company owed the bank in Virginia City about \$40,000. If the Yellow Jacket had reported its indebtedness, as the other Comstock companies do, that investment would not have been made. As soon as those people found out the true condition of the company, they sold their stock.

Charles Butters.—That brings us back to the statement of Mr. Bradley that the reports should contain a statement of liabilities and assets; every directors' report in regard to a mine should be like the statement of any commercial business, giving a true statement of the assets and liabilities. Every English company does.

Albert Burch.—The greatest abuse is the sale of treasury stock, whereby most of the money goes to the brokers, instead of being spent in the development of the mine. Mr. Symmes' suggestion that the cash expenditures should be listed would prevent that

abuse—paying 75% commissions for the sale of stock, 15% to the officers for salaries, leaving 10% for development. A man who buys that kind of stock has very little chance of ever winning.

T. A. Rickard.—Reference has been made to English companies, which are credited with practices a great deal better than American companies; this is generally imputed to the Companies' Acts, in force in England; but, as a matter of fact, such statements as are required under the Companies' Acts would give no more than a perfunctory account of the business of a mine. The reason why English companies, as a rule, give exemplary statements concerning their mining operations is because public opinion in England has been educated up to the point of demanding proper information in proper form. And the best way in which it can be done here is by members of this Society and men like them, who want to act honestly, compelling others by their example to do likewise. No law, if enacted, would be effective unless public opinion gave it momentum. The brutal fact is that many things are done, in Nevada, for instance, that are considered half humorous, whereas in England, where people are not a bit better, they would be considered robbery. In time we shall have the same ideas here; and we shall have them when we get more reports that are as complete and as honest as those of the Alaska-Treadwell, which were modeled in the office of the Exploration Company.

F. W. Bradley.—The financial statements in these reports were modeled by Mr. H. C. Perkins. Some of the forms covering ore reserves, assay-values, etc., have been added in later years.

S. B. Christy.—Mr. Rickard's last remark was that there was no hope of doing anything by legislation. I rather agree with that. If the Government had owned the mines in the first place and had made the giving of correct information a condition precedent to receiving a patent, they would have had everything in their own hands; but that is too late now.

Howard D. Smith.—It seems to me that the legal difficulties are insurmountable, when the Government is unable to get quasi-public corporations like the railroads to give satisfactory statements; they will have to depend upon public opinion or such opinion as this Society and other similar influences can exert to compel the publication of proper reports.

Whitman Symmes.—It seems to me that if the items that have been mentioned in this discussion were all put down, they would not cover more than three pages, and that they would constitute a standard form for mining reports; therefore, it seems to me if our Society had a standard form and we used our influence to get such a standard form into use, it might have a beneficial effect upon mine reports in this country.

T. A. Rickard.—That is a good idea.

W. H. Shockley.—That is a practical suggestion; that is really getting somewhere.

F. W. Bradley.—The members of this Society control the making of a great many reports, as our membership comprises mine managers, consulting engineers, superintendents, and men active in the operat-

ing end of the mining business. Surely we can thrash out some form that we can all agree to use. Such a form would not need to interfere with the particular type of report in use for each individual property, but it could be an addition to such reports, in the shape of one additional page, that would embody the information we consider essential.

T. A. Rickard.—I propose that a committee of three be appointed to prepare such a form of report, to be recommended by this branch of our Society, and that the committee consist of Mr. Bradley, Mr. Symmes, and Mr. Shockley.

(The motion was seconded by Mr. Merrill, and on being put by the chairman, was by him declared unanimously carried.)

S. B. Christy.—How often should such a report be published? If they are published so late as to be obituary reports, they are of no use to anybody except to those inside who have had the information in time to profit by it; that frequently happens, the ordinary stockholder getting the information too late to derive any benefit from it.

Charles Butters.—That would apply more or less to the shifting shareholder. An annual report, if it is well prepared, frequently fulfills all the requirements of a permanent investor.

T. A. Rickard.—What is an investor?

Charles Butters.—A holder of mining shares, a man who holds a mine himself, or who owns shares in a mine. His judgment is guided by careful annual analysis; a short analysis of the operations of a mine, from month to month, is not always as reliable as for a series of years; sometimes the monthly reports are actually misleading. If I myself were interested in a mine I think I should be able to get a better judgment of it by taking a series of two or three annual reports, and I would form my judgment of the value of that property from the comparison of such, rather than from reports for short periods. A report for a short period is liable to be misleading. Of course, if anyone is a speculator 'in and out', he wants a report on the varying value of a mine, because that varies almost from day to day; but the man who makes his living out of the dividends that he gets from mines is safer in not seeing reports too often. For myself, I would rather base my judgment on annual reports than on statements covering short periods.

C. W. Merrill.—I suppose you would add to that some sort of a prediction for future years, would you not?

Charles Butters.—Yes.

M. L. Requa.—In addition to the annual reports, unless it went into details, we might do something like the Southern Pacific and Union Pacific railways, namely, publish a short synopsis of the month's work and add to that a prediction of the possibilities for the coming month. That would simply mean a condensed memorandum. You could put it on a small card.

Charles Butters.—What gives value to annual reports almost as much as anything else is the continuity of the management.

M. L. Requa.—You could add to the value of that by giving a short monthly synopsis. A year is a

long time in the life of a mine, and very material changes may take place in a short period.

T. A. Rickard.—You cannot predicate your suggestions for the regulation of this matter on a supposition that men are going to hold shares in mines for years. You must remember that a great many men are what you call 'in and out' buyers and sellers, and legitimately so.

Charles Butters.—I was expressing one view of it. As a mine owner and holder of shares, my temperament is to hold, and I simply state how I would form a judgment; I should prefer to form a judgment over long periods.

F. W. Bradley.—I think we are losing sight of the fact that there are real investors in mines. As I understand the question, it is addressed to the mine investor, rather than to the man who takes 'flyers'. There are shareholders who do hold mining shares year in and year out, and practically hold the stock to the end without trading in it at all. I agree with Mr. Butters that to such shareholders an annual report is of more value than a report made at more frequent intervals, although such shareholders frequently have issued to them weekly and monthly reports. However, the annual report is what they should be guided by, because they might be misled by all the various fluctuating conditions that are apt to occur in shorter periods.

S. B. Christy.—There is another point that might be mentioned. I believe there would be more investors of that kind if there were more reports on this model. I believe there would be more money invested by people, who, at present, are afraid to go into mining because they are unable to get information. On the other hand, there are a great many mines that do not live long enough to have an annual report.

Whitman Symmes.—In other words, people would come to the conclusion that if a mine cannot have an annual report, it is not a good thing to invest in.

C. G. Dennis.—Should there not be some form of monthly report, from which the annual report could be computed, some advance statement to the stockholders as to the condition of the mine from month to month?

F. W. Bradley.—I think that all mining companies that get out annual reports do get out weekly and monthly reports.

M. L. Requa.—Do those all go to the stockholders?

Whitman Symmes.—According to the State law, the monthly reports have to be on file in the office for the inspection of stockholders. The superintendent has to file a sworn report on the first Monday of each month, and the secretary files a sworn report on the second Monday of the month. These reports supplement the annual report. Sometimes in adding up those weekly and monthly reports, the totals are rather illusory. There are often errors in estimating the amount of labor and the quantity of supplies used in different portions of the work. At the end of the year the different accounts and the costs per unit should be figured back from the total company-expenditure for the year as found on the secretary's books. Timber and other supplies on hand should

also be more accurately determined than is done for the monthly reports. Wear and tear can then be better taken into account. I recall one striking instance that is to the point. When I became manager of the California Vigorit Powder Works, some years ago, I found the company had made out beautiful monthly reports, much underlined with red ink, showing the itemized cost of manufacturing each grade of powder, and the cost of packing it, and the sales-expenses; but when the twelve monthly reports were added up, they presented a cost which was one cent per pound out of the way, or an error of 10 per cent.

S. B. Christy.—There is such a thing as taking too much of the energy of the management in making reports. The annual reports should be filed; the next question is, should supplementary reports be filed at more frequent intervals?

F. W. Bradley.—I think that all mining companies that publish annual reports do get out weekly and monthly reports.

W. H. Shockley.—I thought that the question of reports was pretty well covered by the California law: that they must be filed every week and must be sworn to. If those reports are honestly made they give a great deal of valuable information.

Whitman Symmes.—Our law calls for sworn monthly reports. The superintendent has to state his receipts and disbursements; the number of men employed, and for what purpose, and their rate of wages; the work done in the mine, including all ore discoveries and the assay value thereof; the ore extracted, and from what part of the mine taken; the ore sent to the mill and its assay value; and the bullion received, shipped, and on hand. The secretary has to give an itemized statement of receipts and disbursements, the money on hand, and the indebtedness. All weekly reports from the superintendents have to be filed in the office, and be open to inspection. These provisions are not generally carried out, however. The companies fill in part of their blanks and do not fill in the rest, and their accounts do not always explain for what the money has been expended.

S. B. Christy.—There is one curious thing in connection with California mining: There is comparatively little fraud in connection with it; and over in Nevada, where mining is largely carried on by Californians, it is very different. What is the reason for that?

William Erb.—As near as I can analyze it, the condition is due to a combination of bell-boys, boot-blacks, news-boys, book-keepers, and so forth, being thrown into a boom camp where any mining newspaper will publish their advertisements; the people are invited by the papers to buy stock, and they fall into the trap. It is a matter that must be regulated by public opinion. I have known responsible men, who would not tell a lie, to absolutely evade the issue when asked with reference to certain people, when a true statement would condemn those people for all time. I think that form of dishonesty had more to do with wrecking our boom at Goldfield than anything else. References were given and nothing was

thought about it; they had a stock form of letter, and probably the Eastern end of it had replies dictated that were sent to people making inquiries, and they were handled by really reputable people with no gain to themselves, but thinking the ultimate gain lay within the country and therefore would come to them.

METAL RESOURCES OF THE PHILIPPINES.

The production of gold in the Philippine Islands in 1907 was 4540 crude ounces. At the average fineness of 850, this would represent 3859 fine ounces, valued at \$79,773. The production of silver is given as 83 fine ounces, valued at \$55. Although gold occurs in many islands of the group, the production of 1907 is credited to but two—Luzon and Masbate. In Luzon there are two producing provinces—Benguet in the northern part, and Ambos Camarines in the southeastern part, on the Pacific coast. Masbate island, southwest of Luzon, is part of the province of Sorsogon. In a report published by the United States Geological Survey it is stated: "For centuries the Igorotes of Lepanto and Benguet have been washing gold from the streams or recovering it by impounding water in the hills and releasing it in floods over the decomposed surface of auriferous rocks, and at the same time exposing the rich and narrow veins, which they worked to slight depths. The Igorotes, and later the Spaniards, worked extensively the copper ores at Mancayan, in southern Lepanto, near the northern boundary of Benguet. The ores, which are mixed sulphides, arsenides, and antimonides, sometimes carry as much as \$5 per ton in gold, particularly in the pyrite. In the Camarines, particularly at Paracale and Mambulao, European capitalists at one time did extensive underground work and erected modern mills. Their work was interrupted by the native insurrection of 1896, and has been resumed only in a small way by American miners. During the last year a dredge installed by American and New Zealand capital has made an output of gold most encouraging to the operators, and additional dredges are contemplated for this district. In the northern part of Masbate, at Aroroy, many old abandoned gold mines of the Spanish régime, or of earlier times, have been actively prospected and partly worked by the American miners. Silver ores occur rarely in the Philippines, the one notable deposit being in northern Benguet, near the Lepanto line. This is in part native silver, but the deposit has not been developed. Lead ores carrying silver occur in the islands of Cebu and Marinduque, but they have not yet been developed."

The waste in coal mining is equivalent to about one-half of the total product mined, or, for the year 1907, about 240,000,000 tons. The aggregate of mineral waste for the past year is estimated to approximate \$1,000,000 per day in value. The mineral production of the United States during 1908 was approximately \$2,000,000,000, so that this estimated waste is equivalent to more than one-sixth the value of the total commercial output.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINE-CAR STOP.—No. 907,350. Charles M. Henretta, Bylesville, Ohio.

A car stop comprising a support located between the rails of the track and yieldable lengthwise, a stop block hinged to the support and arranged to swing up or down to stop or pass a car, a trigger supported under the track and normally engaging the block to stop a car, and means to release the trigger.

MINE-CAR COUPLING.—No. 908,880. Thomas C. Nation, Equality, Illinois.

A coupling comprising two vertically swinging members adapted to be interlocked by being engaged at an angle to each other and then brought into longitudinal alinement, said members having portions to engage each other when the members are in alinement in interlocked relation and said members being so arranged that the weight of the same will tend to maintain said portions in engagement and the members in interlocked relation.

ORE-ROASTER.—No. 908,425. Cyrus Robinson, New York, New York.

In an ore roasting mechanism, the combination with the hearth having a discharge passage at its end and a series of two or more openings in its side wall supplemental to the discharge passage adapted to have rabbling tools inserted therinto through said openings in its side walls, of a power mechanism adjacent to the hearth and adapted to detachably engage with and impart vibrations to the rabbling tools, in arcs in substantially horizontal planes while the tools are projecting through the side walls, substantially as set forth.

APPARATUS FOR THE RECOVERY OF PRECIOUS METALS FROM SLIMES, ETC.—No. 893,472. Alphonsus J. Forget, Los Angeles, California.

An apparatus for separating gold or other metals from their ores, comprising a tank, a rotatable circulator located

centrally in the tank for causing vertical movement of the material in the tank, and electrodes in the tank extending tangentially to the vortical movement.

ORE-GRINDING MACHINE.—No. 909,286. George A. Denny, London, England.

A grinding machine comprising a lower stationary cone member having at its apex a bottom inlet and provided upon its inner inclined face with a plurality of longitudinally arranged grinding teeth, a vertically disposed drive shaft arranged above and concentric to said stationary cone member, means for adjusting said shaft vertically, means for rotating said shaft, an upper rotary cone member nested within the lower cone member and provided on its outer inclined face with a plurality of longitudinally arranged grinding teeth, and a gimbal joint connection suspending the rotary cone member at the top from the lower end of the drive shaft.

ORE-CONCENTRATOR.—No. 892,057. Frank G. Janney, Salt Lake City, Utah.

In a concentrator, a rotary reciprocating table having outer compartments for water to receive the material to be treated and having a peripheral rim projecting above the surface of the table, and means for subjecting the water to a jiggling motion during the reciprocations of the table.

FLUID-PRESSURE-OPERATED DRILL.—No. 902,836. Andrew F. Ross, Long Island, N. Y., assignor, by mesne assignments, to The Pittsburg Pneumatic Co., Canton, Ohio, a corporation of New Jersey.

In a fluid pressure operated drill, the combination with a cylinder, of a piston reciprocating therein, a tool rotatably supported by the cylinder in position to receive the impact of the piston, non-rotative direct connections between said piston and the shank of the tool, and means for imparting rotary motion to the piston during its reciprocations.

Publications Received.

Any of the books noticed in these columns are for sale by or can be procured from the MINING AND SCIENTIFIC PRESS.

HANDBOOK OF SMALL TOOLS, COMPRISING THREADING TOOLS, TAPS, DIES, CUTTERS, DRILLS, AND REAMERS, TOGETHER WITH A COMPLETE TREATISE ON SCREW-THREAD SYSTEMS. By Erik Oberg. 12mo., pp. 526, 282 illustrations. New York. John Wiley & Sons. 1909. Price \$3 net.

The merit of this treatise consists in explicitly setting forth the procedure for obtaining the best results by their intelligent application according to the underlying mechanical principles involved. It is thoroughly practical, but also deals with the theory of shop work, giving the basis for calculating the details of work required for desired results, as well as tables from which the data may be taken in most cases by those unfamiliar with the use of formulas. The text is clear and elucidative. As an example of the practical hints, the following extract will be interesting:

"The principle involved in common drill-presses where the drill is given a rotary motion simultaneously with the forward motion for feeding, is the one least adapted to produce a straight and true hole. Better results are obtained by giving only a rotary motion to the drill and feeding the work toward it. It has been found, however, that for drilling deep holes the reversal of this, that is, imparting a rotary motion to the work and the feed-motion to the drill, will answer the purpose better. It seems as if there could be no material difference between the latter two methods. An analysis of the conditions involved will show, however, that there is a decided difference in the action of the drill. If the drill rotates and the work is fed forward, the drill when deviating from its true course will be caused to continue to deviate still more by the wedge action of the tool when the work is fed forward. In the case of the work rotating, and the drill being fed forward, the point of the drill when not running true will be carried around by the work in a circle, thus tending to bend the drill in various directions. The drill is, by this action, forced back into the course of least resistance, as it is evident that the bending action being exerted on the drill in all directions will tend to carry the point back to the axis of the work, where no bending action will appear."

MINING AND METALLURGICAL INDUSTRIES OF CANADA. 1907-08.

This report has been issued to meet the increasing demand on the Department of Mines for information on the mining and metallurgical industries of Canada, which are attracting interest from all parts of the world. The work comprises 936 pages of text, descriptive of all the metalliferous and non-metalliferous mines, and of metallurgical and clay industries in the Dominion; illustrated by 44 engravings and drawings, and mineral maps of the respective Provinces. The maps alone render the report a valuable acquisition. They are up to date as regards the topography of Canada and the positions of known ores and commercial mineral deposits which are being worked are indicated. A brief historical sketch prefaces the industrial review of each Province, and a description of the magnitude, equipment, and mode of operation of every important mine and plant is given; together with the capitalization and personnel of each organization or company. In the copious index some 1500 names of owners or companies are recorded alphabetically. Unfortunately, care has not been taken in regard to the names, many of which are in error. While the report is a directory of the mining and mineral industries of the Dominion, it differs in not being a mere inventory. In addition to the specification of the many mines and industrial concerns, it contains historical notes, geological monographs, analyses of materials, descriptions of equipment, and statistical tables. Inasmuch as the production of the report has been costly, the Department has seen fit to publish it at \$1, so as to ensure it reaching the hands of those directly interested in the practical development

of the mineral resources of Canada. All communications with regard to the report should be addressed to Dr. Eugene Haanel, Director of Mines, Ottawa.

Great Falls Water-Power.

Work is progressing rapidly in connection with the 72,000-hp. development on the upper Missouri river in the vicinity of Great Falls, Montana. The diverting coffer-dam at Rainbow falls has been completed, so that the engineering force can get into the bed of the river to make surveys for the power-house and head-works, and actual construction on the dam is under way. This coffer-dam is built of stone and dirt, and is not intended to be absolutely tight. A second coffer-dam is being built, that will be permanent, and inside of it the actual construction work is being done. Plans for the dam and masonry at the head-gates are complete. Those for the power-station and machinery contained therein will be made later, at the Boston offices of Chas. T. Main, the engineer in charge of the development. An engineering building has been constructed for the engineering force, containing a drafting room, living room, sleeping room, and a bath-room. This building will be steam heated and electrically lighted from a temporary plant. A spur track from the Great Northern railroad has been built into the plant, a distance of 7000 ft. The type of dam which has been designed is a rock-filled timber crib, covering a large area of the bed with a wide apron. The lumber for the dam has been delivered. At the Great Falls of the Missouri the program is practically the same as that at Rainbow falls. The diverting dam is partly built and the surveys in the bed of the river are being made. It is expected that this work will be carried out at the same time as that at Rainbow falls. No contracts will be let, as the Great Falls Water Power & Townsite Co. is doing the work.

Commercial Paragraphs.

The CYCLONE DRILL CO. has recently opened a Chicago office at 419 Fisher Bdg. It will be in charge of J. F. Munn, who has been manager of the core-drill department at Orrville.

The A. LESCHEN & SONS ROPE CO., St. Louis, is distributing an attractive circular which gives several views of the new St. Louis cathedral, the occasion being the fact that more than two miles (exclusive of guys) of Hercules wire rope is in use on the large derricks used in the erection of the structure.

The U. S. FLEXIBLE METALLIC TUBING CO. advises that the San Francisco house has moved to its permanent quarters at 63-65 Main street. The company invites a call from all patrons and friends, and would be glad to show all styles of metal hose carried in stock and to explain the elaborate tests made on all shipments.

The FOOS GAS ENGINE CO., Springfield, Ohio, reports the installation of one of its 36-hp. gas engines and producers at the property of the La Esperanza Mining Co., Zacatecas, Mexico. The plant has been running steadily for two months, requiring an average of 75 lb. charcoal per 24 hr., which amounts to a cost of one cent per horse-power-hour.

Catalogues Received.

The ROBINS NEW CONVEYOR CO., New York and Chicago, in Bulletin No. 1, shows the various uses of the well-known belt-conveyor and the best methods for keeping it in efficient condition.

THE JOSHUA HENDY IRON WORKS, San Francisco, describes in Bulletin No. 14 every variety of its Tangential Water Wheels, from monsters of 50 ft. in diameter to miniatures of half that number of inches. More particularly we notice the wheel designed by J. M. Nicol for heavy duty and high pressure, whereby removing and replacing buckets is accomplished with ease, without sacrificing the rigidity which is necessary to preclude vibration.

EDITORIAL.

READERS of this journal will note a pleasant vein of reminiscence in a letter which we publish this week from Mr. Almon D. Hodges, Jr., where he refers to the late Almarin B. Paul as a "welcome visitor to the office of the MINING AND SCIENTIFIC PRESS." That was many years ago, away back in the sixties, when Mr. Hodges with his splendid German training, came as part of the vitality and power of the new West to the development of its resources, and, among other activities, for a period edited the MINING AND SCIENTIFIC PRESS, giving it a technical importance it has ever since retained. We may add that Almarin B. Paul was not alone distinguished for converting the tedious patio process into a method in keeping with the spirit of the times, but later took the initiative in crushing ores in cyanide solution. He was in the van of progress and lived to see the perfecting of many metallurgical ideas that were evolving twenty years ago and developed into the practice today.

ENGLISH mining companies are proverbially persistent; like the old guard, they may die but they never surrender as long as a chance remains of prolonging the fight for success. Therefore when one mine 'peters out' they take an option on another—somewhere else, anywhere else—for being globe-trotters and also administrators of world-wide empire, it matters not whether the mine be in Burma or Bula-wayo, in Vancouver or Van Dieman's Land. The last name reminds us of the Briseis Tin Mines Ltd., a company operating in Tasmania. Having decided upon "a policy of expansion," the Briseis company instructed its consulting engineers, Messrs. Lake & Currie, to co-operate with its resident manager, Mr. C. Lindesay Clark, in the inspection of gravel mines such as offered a prospect of enlarging the income available for dividends. In consequence, an option was taken on 2000 acres of dredging land in the Yakandandah district of northeastern Victoria, a region already the scene of successful dredging. It is estimated that there is gravel enough to keep four or five dredges busy for eight or ten years, with a profit of 3 to 5 cents per cubic yard in a deposit about 30 feet deep. Having a tin mine nearly exhausted, a cash reserve of £30,000, and abundant credit, this new venture appears commendable. We hope it may prove in every way successful.

OUR New York correspondent mentions the pessimistic tone of the copper market. We confess that the situation does not appear cheerful, for it is known that many important mining companies are holding their product of copper for better prices, thus gradually increasing the threatened condition

of an over-supply. In this connection we may quote the story of a well-informed American who was in London in the latter part of the year and on being asked if a large stock of copper existed in the United States, he confidently answered in the negative. The next day he was invited to meet some prominent bankers who showed him the records of a loan of £5,000,000 on copper stored in New York. We give the story for what it is worth, receiving it from a trustworthy informant. At least, it will emphasize the need of a clear statement concerning the supplies of metal. As yet the Copper Producers Association has done nothing; is it that the truth if published would demoralize the market? Undoubtedly the copper mining industry would gain by being made less dependent on the gambling operations of a metal market, the nature of which is obscured by lack of information. We hope that the leading producers of copper will rise to the needs of the occasion by insisting upon publishing trustworthy statistics.

Destination of Transvaal Gold.

The Rand mines are managed from England, but the remittances of bullion follow the drift of exchange. Thus the destination of the South African gold is frequently determined while it is still afloat, in accordance with the shifting direction of trade-balances. The recent trend of gold has been to the Bank of France. This became pronounced in August last, and has continued so persistently that universal attention has been drawn to the financial power of that country which for the moment seems to be the world's banker. France has been the money-lender to nations in need of help throughout the financial crisis; her resources have appeared to be inexhaustible; nevertheless the stream drawn from her vaults by foreign borrowers would have depleted the stock so jealously guarded in the Bank of France save for protective discounts. The gold reserve has been unflinchingly maintained above \$500,000,000; in spite of enormous loans it stood at the end of January at \$717,000,000. This accumulation had been partly at the expense of the Bank of England, and partly through attraction of the gold remittances from the Transvaal. It is a remarkable fact, unprecedented in the previous history of gold mining, that a single group of mines could be so depended upon for a steady contribution as to be reckoned a definite factor in the forecasts of the money-market. With the regularity of a machine the Rand sends forth its monthly quota of \$12,000,000 in shining bars.

During January the drain upon the Bank of England reserve has been greater than ever, due to preparations for the Russian loan of \$300,000,000, of which only \$30,000,000 at 88¾ had been apportioned to London bankers. Since December 3 practically all the Transvaal gold had been absorbed by Paris. These determined efforts to secure the yellow metal have been attributed by certain critics, with a show of 'inspiration', to political motives, which, if it have any warrant, can only refer to the Moroccan settlement in which Germany has just displayed a complacent mood. The more probable explanation is

the need of maintaining a proper ratio between the reserve and the expanding business relations of France with the rest of the world. As a recuperative measure the Bank of England has been raising the discount rate to divert gold, inclusive of the Transvaal remittances, to London. Raising the discount rate, which is tantamount to making a dearer market for advances of cash, may seem a peculiar way of attracting gold, but it is in reality nothing more than another manifestation of the familiar law of supply and demand; the bank rate increases with the demand; this attracts foreign gold seeking the prevailing elevated rate of interest; and gold so attracted must, under the existing order in the European countries, find its way to the great central banking repository.

Goldfield Consolidated Report.

Among 'Company Reports', on another page of this issue, will be found an abstract of the second annual report of the Goldfield Consolidated Mines Company for the year ending October 31, 1908. This report is disappointing, both as to the information given and as to the manner in which that information is presented. Criticism is proper, for the directors responsible for the issuance of the report are in control of the most important gold mine in America, the shares of the company are quoted on the exchanges of San Francisco and New York, and among the owners of the mine are bankers of high character of whom the best financial methods may reasonably be expected. Moreover, the report is a matter of public interest on account of the 6000 stockholders to whom, in the first place, it is addressed. Viewed from the stockholder's standpoint, this annual report does not afford the fundamental data requisite to an understanding of the condition of the mine. The essential details to which every stockholder is entitled are: a clear statement of the financial transactions during the fiscal year; an account of any work of construction undertaken or completed during that period; a straightforward description of the development of the mine, with a full statement of the results, particularly the prospects on the lower levels; finally, an estimate of the tonnage in reserve and its average value. As regards the first two items, the report performs its duty; but as regards the development of the mine and the ore reserves, the data given are insufficient and unsatisfactory. Thus, in referring to the important question of the persistence of the orebodies below the 400-ft. level, it is stated: "On the 600 level, the lowest level of the mine, an orebody 20 feet wide has been cross-cut and connected by raises with the same orebody on the 450 level, proving beyond doubt that in this portion of the mine good ore is continuous from the upper levels to the 600." The only other information on this point is found in the statement of rich ore extracted from a winze and from a short drift, as quoted in full in our summary on page 262 of this issue. Having regard to the importance of the question of persistence, the stockholders are entitled to more precise information: to an experienced miner the description as

given in the report is not convincing, nor is it adequate. The winze was sunk last April; why is the exploratory drift only 100 feet long? Good ore undoubtedly exists at 600 feet; that is not the only point at issue, but what amount of ore is there on that level, and how does it compare with the 400-foot level? That is the question that every intelligent stockholder will ask. It has been suggested that the orebodies go down like carrots; for aught that the report says this may be true.

It is patent to those familiar with such documents that the frightful discrepancy between the estimate of ore reserves as given in the last annual report and that given this year is the underlying reason for such lack of definition as obscures the report. In our issue of December 21, 1907, we commented on the inadequacy of the evidence given in the first annual report as to the amount of ore in reserve; insufficient evidence warrants skepticism as to conclusions, in mining as in other affairs. In the first annual report the general manager said that "if the bonanza and low-grades are treated together in a mill, I believe there is developed ready for extraction and treatment 1,000,000 tons of an average value of \$25 per ton, which should yield a profit of \$17 per ton." In the second annual report another general manager states that the mine "from the surface to a depth of 400 feet, will produce at least as much as has already been extracted, namely, \$15,000,000." To complete the basis of comparison, it must be added that all the reserves included in the first estimate were in the ground above the 400-foot level, so that the two estimates can stand side by side. In the second appraisal no tonnage is given, for good reasons. In other words, there has been 37,000 feet of development done since the first annual report, \$2,300,000 has been taken out, and yet there is a net shrinkage in estimated reserves of nearly \$8,000,000. On the face of the report, the mine is worth \$8,000,000 less this year than last, without reference to a shrinkage in the probabilities and possibilities below 400 feet. For this result and for the statement obscuring it, we do not blame Mr. J. H. Mackenzie, the general manager. That Mr. Mackenzie was able to get the fact out at all is greatly to his credit, for while it has been known to mine-operators for months, the directors of the Goldfield Consolidated did not publish it to their shareholders.

As to the mine itself, the report indicates in every line that it is in the hands of a capable, cautious, and honest manager. Obviously, in giving reasons for not stating the bare ore reserves, but emphasizing the difficulty of making an estimate and then hazarding an approximation of the gross recovery above the fourth level, Mr. Mackenzie is trying to do the mine justice and to preserve a cautious attitude. Those possessed of experience in such matters will infer from the report that the orebodies are decreasing in richness and size in depth. From the report it is possible by analysis to arrive at the tonnage now available: As 600 tons are to be treated daily, or 210,000 tons annually, and as dividends are promised at the rate of 30 cents per quarter, or \$1.20 per

annum on 3,546,000 shares, making a total of \$4,250,000 in dividends, therefore it is evident that a net profit of \$20 per ton is expected. The working costs are put at \$6 per ton, and if we allow \$2 per ton for development, additional plant, and general expenses, we have a recoverable value of \$28 per ton, from which, allowing a 95% extraction, we infer that the average value of the ore is estimated at about \$30 per ton. Dividing the \$15,000,000 gross by \$30, gives 500,000 tons as the tonnage in reserve above the 400-foot level, that is, enough for two years and four months, or \$2.80 per share in dividends. Add to this about \$1,000,000 of liquid assets or 30 cents per share, we have slightly over \$3 per share assured above the fourth level. It is said unofficially that an extra dividend of 30 cents per share is expected annually; if this be so then the ore reserves will be that much sooner exhausted. If on the other hand our estimate of the average grade of ore is low, then the tonnage is too high. We have made such inferences as are warranted by a slight knowledge of the mine, a wide experience with annual reports in general, and a careful reading of this one in particular. Assuredly, the average stockholder to whom the annual report is addressed will be no better able than we to get at the facts concerning his mine and if any of our inferences are not quite correct, it is due not to prejudice or sinister purpose, only to inability to get information where it does not exist.

With this digression, we come to the ratio between the value of the stock as quoted on the exchanges and the evidence to support the correctness of that appraisal, which is \$8. At this price some \$5 per share must be found below the fourth level, plus interest on the money while that \$5 is being won. Now we can see what the plunger at \$8 per share gets for his \$5 risk. Dividends at the rate of \$1.20 per annum represent 15% on the current quotation. If an 'investor' wants his money back (for every mine has its day) with interest at 8% (and 8% is low enough in all conscience for a gold mine of such erratic orebodies), then the mine must continue to pay this 15% for 11½ years. As there is ore enough for 2½ years above the fourth level, there must be found sufficient for 9 years below that level. As \$15,000,000 is good for 2½ years, then 9 years will require about \$60,000,000 worth of ore, that is, twice as much as has been taken out of the mine *plus* what remains above the fourth level; in fine, the mine must continue to 1200 feet as good as it has been above 400 feet. Everybody who knows this type of ore deposit and who reads the annual report will be aware that there is no warrant for either the belief or the expectation of a continuation below 400 feet, in tonnage and value, as above that level. The prospective value of the mine is undoubtedly great, but when a man appraises that prospective value on the basis of $\$5 \times 3,546,000$ or \$17,730,000, plus interest on this sum, while waiting to get the \$5 back, he is not an 'investor', nor even a 'speculator'; he is a punter with a willingness to give long odds. Either the Goldfield Consolidated is tremendously overvalued or the two annual reports are waste paper.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

A. C. BEATTY is at Los Angeles.

R. H. CAMPBELL is at New York.

ALBERT F. HOLDEN is at Salt Lake.

W. L. LELAND is here from Los Angeles.

H. C. HOWER is on his way to New York.

F. W. BRADLEY has returned from Mexico.

EDWIN J. COLLINS has returned to Tonopah.

JOHN F. ALLEN, manager for the Caucasus Copper Co., is on his way to Batoum, from London.

W. E. THORNE came to San Francisco from Auburn this week.

W. F. FERRIER spent a few days in San Francisco this week. He is now at Kennett, California.

CHARLES W. ABBOTT has joined his father, James W., at Pioche.

J. H. BAKER, now with Phelps, Dodge & Co., is at Fresno, California.

B. H. BENNETTS has opened an office at 3821 North 35th St., Tacoma.

JAMES DOUGLAS passed through San Francisco on his way to New York.

W. R. RUST, manager of the Tacoma smelter, was in San Francisco this week.

B. BRITTON GOTTSBERGER is resident manager for the Tennessee Copper Company.

RALPH NICHOLS is consulting engineer to the Latest Out mine, at Gilmore, Idaho.

T. S. MATHIS of Berkeley, Cal., was at the new camp of Courtland, Arizona, recently.

L. C. GRATON has become statistician for the Copper Producers Association at New York.

G. D. NEVILLE-WYATT and A. T. FRENCH are leaving England shortly for Famatina, Argentine.

ALBERT BORDEAUX has returned to Thonon les Bains, France, from a four months trip in South America.

JOHN H. TALBOT is superintendent of the Calumet & Arizona mines at Courtland, in Cochise county, Arizona.

WHITMAN SYMMES has gone to Virginia City, where he will act temporarily as superintendent of the Mexican mine.

D. M. RYAN has resigned as superintendent of the Mexican Union Consolidated, and Sierra Nevada mines, on the Comstock.

E. W. CARSON, of Los Angeles, has been appointed mine superintendent of the Picacho Basin Mining Co. near Yuma, Arizona.

GUS. A. COENEN has been appointed superintendent for the Walker Lake Gold M. & M. Co. with offices at Sacramento, California.

F. E. STEELE, formerly at Deadwood, S. D., is in the employ of the Creston-Colorada M. Co., at Minas Prietas, Sonora, Mexico.

HOOPER & SPEAK have been appointed general managers of the Great Boulder Perseverance mine in Western Australia. For the last three years the firm has acted as consulting engineer to this mine.

J. PARKE CHANNING, owing to pressure of work as consulting engineer to the General Development Company, New York, has resigned as president of the Tennessee Copper Co., while continuing to be a director of that successful mining and smelting corporation. His office will be henceforth at 42 Broadway.

Obituary.

BERT PETERSON, manager of the El Rayo mines, died at Los Angeles on February 10.

General Mining News.

ALASKA.

F. G. Monley's drill has been closed down for the season, but the Monley holdings will be worked extensively this coming year. On Thanksgiving creek there are 600 ft. of bedrock stripped ready for the first run of water. Jerome Chute, who in the early days of Dawson was one of its largest operators, has acquired large holdings in the Glenn district; on his Eureka creek property, there are 1500 ft. of top-covering removed ready for the spring thaw, and several hundred feet of bedrock uncovered ready to shovel into the sluices as soon as the weather permits. Chute believes that by drilling through the bedrock he may strike a flow of water to use for sluicing. With this idea in view he has installed a drill on American gulch, a tributary of Eureka creek, which will soon be put in operation.

The 'insiders' of the Fairbanks district are delighted at the news from Washington, D. C., that the postmaster general has increased the amount of mail matter which may be carried into the interior in winter time. The increase allowed is 48,000 lb., and will certainly be taken advantage of, as loads of mail have often had to wait for the opening of the summer service.—A copper nugget weighing three tons will be exhibited by Alaska at the Alaska-Yukon-Pacific exposition to be held at Seattle.—Numerous reports have been heard of rich strikes being made in the Koyukuk country. H. P. King, of Cordova, writes how satisfactory the developments on Nolan creek have been. Pay dirt has been found for two miles along the creek, and the benches on the left limit are showing up well.

ARIZONA.

COCHISE COUNTY.

The capacity of the Southern Arizona Smelting Co., which at the present time is 700 tons, will be increased to 1400 tons daily. When the Sascu smelter was built its capacity was but 300 tons. A second furnace was added, giving a capacity of 700 tons. This amount of ore is furnished from the Imperial mines and custom ores cannot be treated. In fact the mines can supply more than the smelter is able to handle.

GRAHAM COUNTY.

The Arizona Power & Water Co. has just been incorporated in Arizona by D. M. Potter and G. F. Reed. The company proposes building two large dams above Clifton for the purpose of generating power for any who require it. The first dam on the San Francisco river will be 100 ft. high, unless present plans are changed. Eight water appropriations have been secured, four of which are on the San Francisco river and four on Black river, which no doubt are sufficient to meet all future demands.

MOHAVE COUNTY.

A 10-stamp mill has been hauled out to the mines of the Expansion Gold Mines Co. at Union Pass, where it will soon be installed. It is the intention of the company to put in a complete plant, capable of treating 40 or 50 tons per day, and later, when sufficient water for a large plant is developed, more stamps may be added.—L. Hoffman, who has been examining the mines of the Arizona Southwestern Copper Co., reports that the water coming from the mine is so strongly impregnated with copper that tools in the shaft are almost instantly plated with the red metal.

PINAL COUNTY.

D. C. Jackling has been appointed general manager for the Ray Consolidated Copper Co. He now holds that same position with the Utah Copper Co., and will design the new smelter on a modified plan of that at Garfield. The smelter will be built in sections so that the same plans can apply to a 500-ton as to a 3000-ton smelter. To increase the capacity sections will be added as required.—The Copper Creek Mining Co., adjoining the Calumet & Arizona near Mammoth, is busy at construction work under the management

of Roy Sibley. It is now erecting a 500-kw. central power-station of which the first unit has just been completed. It is also constructing a concentrating mill, which will have a capacity of 250 tons daily. At the top of the 3-compartment shaft is a fine double-drum electric hoist, and all the rest of the equipment is on the same scale.

YAVAPAI COUNTY.

The Maguire mines have been sold by A. J. Pickrell to the directors of the Arizona Gold Mines Co., and the final payment has been made.

YUMA COUNTY.

The Arica group of gold mines, in the Parker district, has been bonded by the Williams brothers, from Mrs. C. H. Gray, of Phoenix, who is the principal owner. The vein at a depth of 190 ft. is said to be 6 ft. wide.—Ames Sterling, former head of the Australian geological survey, is examining the geology and petrology of the Clara Consolidated Gold & Copper Mining Co. for the manager, George Mitchell. Progress is being made by that company in the preparation of its smelter site, and nearly all the machinery is on the ground.

CALIFORNIA.

ELDORADO COUNTY.

Nearly 100 mining location notices have been filed with the County Recorder since the first of the year.—R. E. Garetson, C. McClellan, and others, who recently bonded the old Gray mine near Shingle, have bonded the Golden Hatchet gravel mine, on Webber creek.

INYO COUNTY.

As a result of the recently held annual meeting of the Four Metals Co. at San Jose, orders have gone out to double the furnace capacity of the smelter at Keeler. A gasoline engine has been ordered for the mine to augment the steam engine already installed there, and an extension of the electric line of the company on Lone Pine creek has been made. Power will be generated at Lone Pine and Keeler for public use. The smelter when enlarged will have a capacity of 300 tons daily.—Some ore from the 160-ft. level of the Bishop Creek Gold Co. has been tested by Ricketts & Banks, of New York, to find its suitability for treatment by cyaniding. They used the new Moore-Clancy process, and obtained an extraction of 90% on the ore, the heads of which ran \$20 per ton.—Three tons of \$600 silver ore have been brought by George Cook to Keeler from Nemo canyon in the Skidoo district. The forty miles of road are in fair condition.

NEVADA COUNTY.

The lower adit at the Magnet is in 500 ft. and is advancing rapidly. Driving is being done with machine drills operated by air compressed by water-power from Canyon creek. Cross-cuts will be driven from the main adits to intersect the parallel veins. Frank L. McPherson is superintendent.

PLACER COUNTY.

It is reported that A. Maltman has been appointed manager of the Three Stars mine and that he has begun pumping out the shaft. Maltman lives in Grass Valley and is also manager of the Ethel mine in Nevada county.

SHASTA COUNTY.

The First National Copper Co. has three furnaces in blast at Redding, giving a total capacity of 1500 tons per day. All of the equipment is new and the converters have not been operating long enough for the company to determine how high grade a matte the furnaces will yield. The company is handling the ores of the Trinity and Balaklala Copper companies, the Balaklala ores being handled as part of the company's properties, while the Trinity ores are handled as custom work. In addition, silicious ores are being drawn upon from several of the Nevada camps. A more favorable rate for the shipping of quartz ore to smelters has been announced by the Southern Pacific. Heretofore the least charge has been 75¢ per ton. Following are the new rates for car loads of at a minimum weight of 15 tons. From Redding to Kennett, Keweenaw, Coeur, and Pitt, ore

not exceeding \$10 per ton, 50c. per ton; over \$10 to \$30, 75c.; over \$30 to \$50, \$1; over \$50 to \$100, \$1.20.—An electric locomotive has arrived for the Hazel Creek Gold Mining Co., to be used in the Gladstone mine at French gulch. The main working tunnel of the Gladstone is 4000 ft. long, and strikes the vein at a depth of 1000 ft. from the surface.

SIERRA COUNTY.

W. F. Sherwood and M. Green have taken a bond on the Bullion quartz mine near Sierra City. The Bullion was formerly called the Colombo, and has had some good rock extracted in the past. Work will be commenced early in the spring.—Some rich 'specimen' rock has been taken from the shaft at the Red Star mine at Alleghany. Rich rock has been taken from several places in the tunnel during the past few months, but this is the best they have ever come across.—The extra five stamps have been put in place at the Papoose mill and now ten stamps are kept constantly dropping on good rock. John Taylor is in charge of the mill.—The gasoline engine that is used at the No Better shaft at Forest has got obstinate again and refuses to work. The management has been forced to cease operations until it is repaired. At present the shaft is about 175 ft. deep.

TUOLUMNE COUNTY.

The Nerry Gold Mining Co. has the distinction of having a lady as president. Miss F. M. Colby is spending a good deal of money in developing her property near Columbia, and now has at least 500 ft. of backs ready to take out. The old mill on the Nerry is useless, but Miss Colby has secured from Conlin Bros. a bond on their holdings at Italian Bar, including the Golden Era mine and mill.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Griffith group of mines on Griffith Mtn. was sold this week by order of the United States District Court at Denver. The property was bid in by W. D. Hoover, of Denver, the principal owner in the defunct Griffith Mines Co., the consideration being \$65,000, the full amount of which was paid in cash. Mr. Hoover is now organizing a new company to clean out the old levels and re-timber the stopes and drifts. Work is shortly to be put under way upon the construction of an electro-chemical milling plant with a capacity of about 50 tons daily.—To satisfy a judgment obtained from the District Court of Clear Creek county on January 6, 1909, the sheriff has sold to F. C. Pannill and W. J. Kie the Little Flat group of claims situated at Idaho Springs in the Jackson district. The property brought the sum of \$8092. It is reported that a new company is being organized to develop their new acquisition.—A number of tests have been made lately at the Georgetown adit in running a Sigafos tunneling machine, which consists of a frame carrying ten cutting or crushing heads that strike by means of a spring, and work on the whole face of a drift at the same time. As yet the pumping station has not been put in operation, and until plenty of water is available it will be impossible to state with any degree of accuracy the results obtainable. However, ground has been broken at the rate of one inch per minute. A big force of men is being employed, both by the Georgetown M. T. P. & T. Co. and the American Rotary T. M. Co., and it is hoped to have everything in readiness for the real tests during the next few days. The machine, which weighs 56 tons, is now about under cover, showing that it has already drilled nearly 20 ft.—Word was received in Georgetown this week that work will at once be resumed in the Kelly adit, the entrance of which is situated on Democrat Mtn. within the corporate limits of the town. It is understood that a working fund of \$60,000 has been provided. All outstanding indebtedness has been liquidated by the manager, Jerome Smith. The 50-ton concentrating mill will also be put into commission on ores from both the Moline and Boston adits. In the drift run on the Boston vein a body of lead ore is exposed that is from

2 to 5 ft. wide, and worth from \$55 to \$60 per ton in silver, lead, and zinc. On the Deming vein there is showing a body of mill ore that is from 5 to 9 ft. wide, worth from \$14 to \$16 per ton. The aerial tramway is to be repaired to permit of the prompt delivery of the ore to the mill-bins. The Kelly adit is now in a distance of 2800 ft.—The Commonwealth vein was recently cut by the Wilcox adit, and showed lead ore from 12 to 16 in. wide, worth \$55 per ton in silver and lead. In sinking a winze on the same vein a streak of smelting ore has just been exposed that is from 2 to 3 ft. wide. D. F. Sprouse states that shipments will be discontinued until the Argentine Central railway has been opened for traffic in the spring. The 125-ton concentrator is running steadily and is treating ore from the Wheeling vein.

Georgetown, February 6.

LAKE COUNTY.

The property known as the Forest Lode claim, owned by the New York & Texas Gold Mining Co., was sold several years ago for delinquency of taxes, and has never since been worked. Now considerable interest has been aroused because it has been purchased by Osborne A. Butcher, of London, England; and it is wondered if discoveries of ore have been made.

TELLER COUNTY.

The new plant at Stratton's Independence began operations shortly after the new year, and has been running light for about fifteen days. During this period the general manager, Philip Argall, reports that 500 tons of \$7 ore were treated. The machinery is adjusting itself and the tonnage to be treated during February will be materially increased.—The output of the Cripple Creek gold mining district for the month of January reached the total of 61,728 tons with a gross value of \$1,362,274. As compared with the closing month of 1908 a decrease is shown in tonnage of 6272 tons, but with an increase in value of \$2200.—A cave on the second level of the No. 1 property of the Portland mine completely filled the 'Queen of the Hills' stope. No one was injured when the rock fell, as the stope has been abandoned for some time, but the immense dump above the caved portion sank several feet and it is estimated that 8000 tons of dump fell through.—H. P. Dahl, of Cripple Creek, owning and operating the Coriolanus mine on Battle Mtn., has started a cross-cut from the north-eastern lateral of the United Mines tunnel to a point under the shaft, from which he will raise 100 ft. to connect. Ventilation will then be perfected and it will be possible to operate 650 ft. from surface.—The lease on the Mable M. and Gold Dollar mines on the eastern slope of Beacon hill, formerly held by the Beacon Hill Mining & Development Co., has been formally transferred to the Union Leasing Co. C. G. Jackson will continue as superintendent for the new owners.—A gasoline hoist is to be installed at the main shaft on the Morning Star mine on Bull hill, by the Morris brothers, of Cameron, the lessees. These operators have opened up a promising orebody at a depth of 250 ft. and will shortly resume shipments. The property is owned by the Acacia Gold Mining Co.—Schwartz & Co. recently secured a lease on the dump at the Gregory shaft of the Elkton Consolidated Mining & Milling Co.'s Princess E. mine on Raven hill. A small milling plant is to be erected with solution tanks to treat about 25 tons daily. The dump accumulated for the most part during the time of the Hayden lease.—At the annual stockholders' meeting of the Portland Gold Mining Co. the old board of directors, with Frank G. Peck as president, was re-elected. The report shows a gross production for the year of 94,311 tons having a gross value of \$1,834,080, the average value per ton being \$19.45. The total expenditures were \$1,278,029, making the net earnings \$588,839, out of which amount \$480,000 was paid in dividends. The company has been trying the Tippet-Crowe and Moore-Clancy processes on its ore and also a process which will be known as the Portland process. These tests have sufficiently demonstrated that crude ore can now be treated, thus effecting a saving of 76 cents per ton for

roasting and \$1 per ton for transport to Colorado Springs. The company now proposes to erect, at an early date, a 300 or 500-ton mill at Victor to put the Portland process into practical operation.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—A circular letter has been issued to the stockholders of the Amador company advising them to meet the assessment of two cents per share which falls due on February 15. It is stated that both the mine and the smelter are in good condition and that but few repairs will be necessary to the railroad. To date upward of \$25,000 has been collected on the assessment. Another letter to much the same general effect has been issued from Chicago. The latter of these two circulars states that all the charges made against the manager have been investigated and found to be untrue.—Work is about to be resumed on the property of the Iron Mountain Tunnel Co. which lies just across the Idaho-Montana State line. It is the intention to clean out the old shaft and cut a station on the 1600-ft. level and then to install machinery. The company has paid out over \$1,000,000 in dividends.—A 15 foot vein of copper ore has been disclosed by the diamond drilling recently begun on the Missoula Copper company's property in the Mullan district. The core was extracted from a northwesterly direction from the face of the adit, and another hole will be bored in a northeasterly direction to prove the length within reach.—A 25-foot vein carrying lead and silver, some of which assays as high as 63% lead and 23 oz. silver per ton, has been opened up in the property of the Iron Mask Co. The vein was cut at the end of a 900-ft. cross-cut and has been drifted on for about 100 feet.—Four feet of good concentrating ore has been opened up in the property of the Amazon-Dixie Mining Co. operating a group of claims in the Lookout district. The ore was found at the end of a 525-ft. drift and at about 200 feet from the surface. The ore assays 18% lead and 7 oz. silver. In May an 1100 ft. adit will be started at a point 36 feet from the tracks of the Northern Pacific railroad and 2000 feet east of Copper creek. The company will erect new boarding and bunk houses, two concrete dams—one on the St. Regis river and one on Copper creek—connecting with the power plant by means of a 9000 ft. steel pipe. At the same time the present compressor will be taken out and one of at least 10-drill capacity installed. The cost of the improvements will be between \$25,000 and \$30,000.—A force of men has been set to work to dig out the machinery recently covered by a snowslide at the property of the Full Moon mining company. If the men are successful in this work development will be resumed at once; but if the machinery cannot be rescued at this time, work will have to be resumed by hand.—Patrick Burke and his associates, who took an option some time ago on the Oro Fino group of claims near Murray, have made a first payment of \$10,000. The option involves the sum of \$40,000 and the final payment of \$30,000 is to be made by November. It is believed that the property will ultimately be consolidated with the Black Horse Mining Co. of which Burke is president.—The famous tailing suits, affecting almost every producing mine in the Coeur d'Alene have at last been finally settled, according to a telegram received by C. W. Beale, the attorney for the mining companies. This telegram stated that the United States Supreme Court had denied the application for a writ of certiorari and had ordered the cases dismissed. The application for the writ was from the Circuit Court of Appeals at San Francisco which had decided against the ranchers. It was sought to have the Supreme Court revise the proceedings and this was denied. The cases were those of Timothy McCarthy and others v. the Bunker Hill & Sullivan, Hecla, Snowstorm, and Federal Mining & Smelting Co.'s mines, and involved an application for injunction based on the claim that the tailing from the mines which had been dumped into the Coeur d'Alene river had poisoned cattle and rendered ranch land unfit for agricultural purposes.

Wallace, February 3.

MICHIGAN.

The Tamarack Mining Co. will institute diamond-drill operations on its Cliff property, at a point about half a mile north of the Ojibway No. 1 shaft. This portion of the company's property has already been thoroughly explored, so it is supposed that this is for finding a suitable position for a shaft site.—The Michigan Copper Co.'s stamp-mill on Keweenaw bay will be completed in about three months. The machinery is all on the ground and a large part of it has already been erected.—The vertical shaft of the Hancock Mining Co. is now being sunk below the fourteenth level and the cross-cut east to connect this shaft with No. 1 is progressing at a rate of 200 ft. per month. It is expected to have the two shafts connected by April.—Adventure is still searching for the Lake lode which the Lake Copper Co. is working so successfully. The lode is supposed to traverse the south side of the company's holdings and much drilling has been carried on. Ten holes have been bored and three veins intercepted that give some promise. But so much do these three veins resemble on another that it is difficult to determine the one sought.—The annual report of the Copper Range Consolidated Co. for the year ending December 31 shows a creditable record for Baltic and Champion, while Trimountain and the Globe have been distinctively disappointing. The two first have each been producing about 70,000 tons per month, running 22 to 23 lb. copper per ton. Trimountain has been so low-grade that the cost per pound of the copper produced was about equal to the selling price, leaving no profit; and the Globe property has been finally abandoned after an expenditure of \$600,000. However, the combined operations of the company have been successful enough to enable them to pay dividends of \$4 per share. Diamond-drill exploration is in progress near Mill Mine Junction, where hopes are entertained of cutting the extension of the Atlantic lode.

MISSOURI.

JASPER COUNTY.

The severe wind storm which swept over the district last week caused a great amount of damage and forced a number of the mills to close down until repairs could be made. Elevators and tailing flumes were blown down and in the case of old and poorly constructed mills more serious damage was done—at times even the roofs being torn away. The storm will have caused a curtailment of the production for the week.—Among the new mills recently built is a sludge mill on the Cameron lease southwest of Joplin. This sludge mill is unique in many respects, as new methods are employed for treating the tailing and sludge. Its work is being watched with interest as it is hoped that a large amount of the slime-ore usually lost will be saved.

NEVADA.

ESMERALDA COUNTY.

The Nevada Black Marble Co. has started shipments from its quarries near Mina, sending the material to San Francisco. The deposit covers about 60 acres, it is claimed, and present cutting has opened it to a depth of 200 ft. Another deposit of marble in the State lies in White Pine county, not far from Gandy, but is a white and gray marble.—Active development will soon be re-commenced by Charles Worden on the property of the Marguerite Mining Co., about seven miles east of Walker Lake. A shaft has already been sunk 125 ft., disclosing 16 ft. of ore that averages from \$12 to \$16 per ton at the 60-ft. level. The deposit occurs at a contact between granite and limestone.—The Chamber of Commerce of Goldfield has received notification from the directors of the American Mining Congress that the next annual meeting of that body will be held in that city, thus ending the struggle waged by Seattle, Douglas, and other Western cities for the honor.—For the 10 months ending with January 1, 1909, the Pittsburg-Silver Peak Co. mill at Blair has averaged a monthly tonnage of 10,000 tons, with a value of \$10 per ton. Of this amount 63% is saved by amalgamation on the plates, the cyanide plant effecting a

saving of an additional 30%. The output in this period amounts to \$930,000. At the mine 153 men are employed, with an additional 80 in the mill, machine, carpenter shop, and on outside work.—The directors of the Rawhide Coalition Co. have granted a number of leases extending for a period of five years, which provide that the lessees must erect several mills and in addition develop the mines down to a depth of 500 ft.—Contracts have been closed by G. Vickers with the Woods-Sullivan Co. for a complete new 75-hp. equipment, including a double-drum electric hoist, skips, etc. This plant is for the Little Florence lease on the Combination Fraction, and the present 40-hp. gasoline hoist on the ground will be sold. The new equipment will enable the company to operate nine drills instead of three.—It is reported in Goldfield that the Diamondfield Daisy will resume shipments next week. The Daisy has not shipped for more than two months, but the superintendent, Charles Wilkinson, is confident that he can now maintain a steady output.—At the new mill of the Florence Goldfield Mining Co., 90 tons of ore from the dump are being treated per day. It is hoped that the additional 20 stamps, or a complete battery of 40, will be running within a short time. Three shifts are being employed, and the number of men will be increased as conditions warrant. After the dump ore is all treated, rock from the lease workings will be handled.—The first bar of bullion has been sent out from the new Florence-Goldfield mill. A saving of 65% is being made on the plates. Nearly three carloads of concentrate are ready for shipment, and the cyanide plant is doing good work.

LANDER COUNTY.

At the Shoshone Quicksilver mine, two miles from Ione, two retorts of six ovens are being operated. The output at present averages between 400 and 500 lb. of quicksilver per 24 hr., and they have about nine tons of mercury in flasks awaiting shipment.

LINCOLN COUNTY.

John A. Kirby has received bids for the farther sinking of the shaft of the Pioche King Mining Co., and will shortly give the contract for a 50-hp. gasoline engine.—George E. Cox has made good progress with the shaft of the Gold Prince, as he is now down nearly 300 feet.

NYE COUNTY.

New refining furnaces are being installed in the Montana-Tonopah mill for the reduction of the cyanide precipitate to bullion. Previously these have been sacked and shipped by express, and it is believed that sufficient saving may be made by expressing bullion instead of precipitate to pay for the expense of the installation.—Harry Stimler and William Marsh, pioneers of Goldfield, have located a new gold camp in the Monitor range, 30 miles northeast of Tonopah.—The new ore rate at the Needles smelter has gone into effect. Ore from the Goldfield district will be handled at a reduction of \$2.60 on \$40 ore, and \$2.75 on \$15 ore. Ore from the Bullfrog district will be handled at from 50c. to \$1 less than that from Goldfield. Other districts along the line of the Tonopah & Tidewater railroad will be similarly benefited by the reduction.—The Aldrich electric pump for the Tonopah Mining Co. has arrived and is being installed at the 1200-ft. station in the Mizpah shaft. All the 16-in. pipe arrived several days ago. The pumping capacity is 2000 gal. per minute and the pump is expected to handle all the water coming into the shaft.—The Bullfrog Chamber of Commerce is applying to the members of the Senate and Assembly of the State of Nevada to divide the county of Nye into two parts, at the Mt. Diablo base line. The Chamber of Commerce claims that the county is too large for good and economical government, and that the southern part has sufficient taxable property to support a compact well-managed administration.—All the machinery for the Kanrohat mill in Jefferson canyon is now at the mill-site. A force of 30 men is busy placing the two 5 and 7-ft. Huntingtons and enclosing the mill building. B. Jacques is in charge of the work and hopes to have the mill in operation by April 1.

STOREY COUNTY.

Due to the fact that a number of the miners have been put to work re-timbering the destroyed portion of Sutro tunnel, the Comstock output for the week fell off to \$13,764, or nearly \$2000 less than last week. Of this amount Ophir goes on record for \$10,506.

NEW MEXICO.

GRANT COUNTY.

The Ridgewood claim at Sylvanite has been secured by E. L. Haff, consulting engineer, acting for the Eureka Sylvanite Mining Co. In addition to this the company has purchased the Euclid claim adjoining the Ridgewood, and the Jumbo claim adjoining the Pearl on the north, and this, with the Venus, Neptune, and Lakesight all owned by the company, gives them 240 acres of mineral-bearing ground. The officers of the company are: C. H. Morse, late of Cripple Creek, president; William B. Root, late of Denver, secretary and treasurer; Edward L. Haff, consulting engineer, and S. Camp is general manager of the property.

OREGON.

BAKER COUNTY.

August Mathez has been checking up the ore reserves of the mines of the Commercial Mining Co., in which Samuel Newhouse recently secured a large interest. Better results are being shown than were secured at the time the original inspection was made. The ore-shoot shows 12 ft. of \$47 ore, the breast of the workings giving 6 ft. of \$120 ore, and the deepest workings show 14 ft. of \$16 ore.

UTAH.

SALT LAKE COUNTY.

A bill has been introduced into the Legislature to create an Office of State Mines, with an inspector who shall have jurisdiction over each and every metal mine in the State, and shall visit them at least once in every three months. The bill's number is 42, and is being introduced by Holman, of Salt Lake.—The U. S. S. R. & M. Co. are putting 1280 more sacks in the baghouse at Bingham Junction to more completely remove all the particles in the gases which are considered detrimental to vegetation and animal life. The original plant consisted of 2100 bags, and was the means of securing permission from the courts to continue the operations of smelting the silver-lead ores.

The Utah-Apex Co. is now in charge of the Phoenix Mining Co., and the Phoenix mill has begun to turn out concentrates for the Utah-Apex Co. The mill at present is treating 50 tons of crude ore per day. The company is shipping between 50 and 60 tons of first-class ore direct to the smelters. About three weeks ago connections were made with the Boston Consolidated spur railroad, and now all first-class ore shipped by the company is handled without the use of horses and teams. The gross earnings of the company are now estimated at about \$1800 per day.

WASHINGTON

FERRY COUNTY.

(Special Correspondence).—The New Republic Co. has reported having 32 men on its pay-roll, of whom 22 are breaking ore in the Republic mine. The mine is being gradually cleared of debris from the caving in of the several levels, since it was closed down, in the fall of 1901. The caving had made the first, second, and third levels almost inaccessible, but the cleaning up has done much toward revealing several valuable deposits that were either in sight when the mine was closed down or have been exposed by the caving. The first carload of ore shipped by the new company assayed \$74 per ton, or a gross value of \$3848. So far no returns have been made by the smelter. Ore is being mined in several places on and above the fourth level.—The lessees of the south end of the Surprise claim, belonging to the Pearl Con. Mining Co., have drilled through from the new workings into the bottom of the shaft and drained off the water. They are now raising to make a working connection.—Five men are employed on the lease of the In-

surgent mine. The lessees shipped 32 tons of ore, making the seventeenth shipment since the beginning of the original lease. The first work done by the lessees consisted in driving an extension of the lower adit of the Pearl Consolidated Mining Co., on the Lone Pine vein, following it into the Insurgent ground.—The Belcher mine is being operated under the supervision of Bruce White, former manager of the Slocan Star, in West Kootenay, B. C. He has been at the Belcher mine since last November, and is now engaged in development work with 12 men. He has driven through 50 ft. of payable ore on the No. 2 level and is now blocking it out to determine its size. The ore taken out is piled on the dump, there being no present way of shipping it. The assay office at the mine is in charge of A. H. Burns, who was formerly with the Bunker Hill & Sullivan Company.

Republic, February 3.

William Scheck, manager for the Germania Tungsten Mining Co., owning 2000 acres of land in Stevens county, has closed a contract with steel manufacturers in Germany for the entire output of the property. The 40-ton mill will be enlarged and operated to its full capacity and the force will be increased to 50 men. The company plans to build a road to Springdale, the nearest shipping point, thus reducing the haul to 12 miles instead of 20 miles as at present.—The report of the United Copper Mining Co. states that there are approximately 200,000 tons of ore in sight

Map of Washington.

and that of this, 100,000 tons has a gross value of \$10 per ton. Six thousand feet of development have been done, and of this 2965 ft. were accomplished in 1908. Three thousand tons of ore were shipped in 1908, and there are now 200 tons of ore broken ready for shipment. Conrad Wolfe is president and manager; Gale Smith is treasurer; and the property is six miles from Chewelah.—A new process of smelting copper ore has been exhibited at West Seattle during the last month. The furnace itself is built of brick, is 20 ft. long, 7 ft. wide, and 8 ft. high, lined with firebrick, containing two hearths sloping from the extreme ends of the furnace to a well at the centre, from which the matte and slag are tapped, and has a capacity of 25 tons per day. Crude oil and steam at 90 lb. pressure are admitted and combine in the ore chamber just above the charge, in such a way that roasting is in progress at one end of the furnace and smelting at the other. The process is stated to be continuous.

WYOMING.

CONVERSE COUNTY.

Edwin Hall, general manager for the Copper Belt Mines Co., states that the company's shaft, south of Lusk, is now the deepest in the State, having reached a depth of 620 ft. The ore-shoot was lost at a depth of 280 ft., but the shaft was continued and again struck ore at a depth of 600 ft. The company is now shipping its sulphide ore. The Copper

Belt is in a new district, north of the Hartville iron and copper region.

CANADA.

BRITISH COLUMBIA.

For the purpose of taking over the Kootenay Chief and Comfort mining claims, near Kootenay Lake, J. A. Whittier and Louis Pratt have organized the Kootenay Chief Mines Ltd., with a capital of \$500,000 in shares of \$5 par value. The head office of the company is at Kaslo.—William M. Williams, familiarly known among the miners as 'Black Billy', one of the pioneer gold-seekers of British Columbia, claims to have discovered veins of platinum ore on his property in the Teague group of claims, some thirty miles south of Hope.

MEXICO.

Pedro Alvarado, owner of the Palmilla mine, now operated under lease by an American syndicate, has formed a company to take over many mines of the Parral and adjacent districts in Chihuahua. It is stated that over 70 mines are embraced in the merger, and that the company will have a capital of \$25,000,000. It will be financed in Mexico and the United States and incorporated under the laws of New York.—The unwatering of the old workings of the San Cayetano mine, owned by the San Cayetano Mines Co. at Guanajuato, is progressing under the direction of William Tanguay, superintendent, and Frederick H. Clark, the general manager of the mine. This unwatering will affect not only this mine, but will also drain two of the mines of the Reduction & Mines Co., whose workings are adjacent.—C. B. Bell has made the first payment to Carlos Soto for the Monte Cristo mine in the Lampassas district of Sonora, in the sum of \$50,000. Bell's partners in his purchase are C. H. Jones and Frank Douglas, and the total sum to be paid to Soto amounts to \$400,000. Soto worked the mine himself for many years, but so irregularly that the development was not properly kept up to pace with the extraction of ore.—A bill has been prepared and introduced into the Mexican Congress, under the direction of the Department of Mines, for the purpose of advertising the mineral resources of the Republic of Mexico. Under the provisions of the bill as introduced, exhibits such as the Mexican Central now displays at Chihuahua, will be established at Juarez, Torreon, Zacatecas, Aguascalientes, Queretaro, and Mexico City.—Potter Palmer, of Chicago, has purchased the Promontorio silver mine at Cusiuhiriachic, in Chihuahua, for \$250,000. The former owners were F. Delgado and B. Barcenas, of Guadalupe. This mine is 13 miles from the Chihuahua & Pacific railroad, and has only been worked in a small way during the last four years.—H. Lawrence Read, of Australia, has formed a company in England for the purpose of exploiting the Potter process in Mexico, and will establish an ore-testing plant in the vicinity of the City of Mexico.—Three properties in the Naica district, the Cia. Minera de Zola, Cia. Minera Sensitiva, and Cia. Minera Carolina, have been organized in Parral as a new company under the name of the Cia. Minera Emilio Zola y Anexas de Naica, S. A., with a capital stock of \$200,000, divided into 4000 shares of a par value of \$50.—The International Smelting & Refining Co. has purchased the plant of the Compañia Metalurgica de Torreon, on the recommendation of E. P. Mathewson and D. L. Ricketts, who lately reported on its condition.—The Ajuchitlan Mining & Milling Co., at work near Ahorcado, in the State of Queretaro, has been operating by electric power, taken from the Queretaro Power Co., with extremely efficient results. The company has ordered from G. & O. Braniff & Co., agents for the Westinghouse Co., several new motors, transformers, circuit-breakers, etc., and is also installing a new electric pump.—The San Francisco del Oro Mining Co., operating in the Santa Barbara district, Chihuahua, has suspended operations and will be reorganized.—The Green Gold Silver Concession having raised the Department of Finance to throw the territory open for the filing of mining claims on February 8. There has been a rush of prospectors to the district to take advantage of the opportunity.

Special Correspondence.

JOHANNESBURG, TRANSVAAL.

Summary of Conditions in 1908.—Policy of Consolidation.—Metallurgical Practice.—Stope Drill Contest.—Mining Commission.

The year 1908 has been marked by so many notable events which have furnished good cause for satisfaction, and progress in all branches of the Rand gold-mining industry has been so substantial, that it is only possible to cover the outstanding features quite briefly, within the limits of this fortnightly contribution. Summarized, the following are the chief points calling for notice: (1) Increased aggregate tonnage, owing to the rise of new producers, to stamp-battery extensions, and to further addition of tube-mills. (2) Increased total yields and profits. (3) Reduced yields and costs per ton. (4) Share-market improvement and consequent financial activity, providing funds for sound schemes of expansion. (5) Good deep-level developments in the Central and Far Eastern Rand. (6) Greatly improved labor conditions, despite Chinese repatriation. (7) Numerous mine consolidations. (8) Erection of central electrical power-stations. (9) Drafting of a new gold-law and the publication of mining commission's report. (10) Modifications of mining and metallurgical practice.

At the time of writing, statistics for the whole year are not complete, but gold production is not sufficiently steady to enable the totals to be estimated with absolute accuracy. Output and dividends for the Transvaal since the war display the following record of progress:

Year.	Yield.	—Dividends—	
		Total.	Percentage of Yield.
1902	£7,301,501	£2,121,126	29
1903	12,628,057	3,345,502	26½
1904	16,028,883	3,877,624	24
1905	20,854,440	4,832,436	23
1906	24,616,704	5,735,161	23
1907	27,403,738	7,131,212	26
1908	*29,700,000	8,748,612	*29½

*Estimated.

The high percentage of the yield available for distribution in 1902 was largely due to the fact that only the richer mines were re-opened at first, so that the 1908 proportion is significantly creditable, being the dividend-margin upon the working of comparatively low-grade ore. Throughout the period there has been a gradual fall in grade consequent upon the growing activity of poorer mines and upon the policy of cutting down costs so as to bring the poorer parts of all mines into the range of probability. Thus it will be gathered that the tonnage of ore has risen more rapidly than the yield of gold. At the beginning of 1907, the yield per ton averaged 34s., at the close of 1907, 33s., and today it is 30s. 6d. per ton. This fall is simply due to the change in industrial conditions, and provides the apostles of pessimism, who have so frequently attempted to dishearten the ignorant with alarming predictions of a consistent fall in the value of ore with increasing depth, with no cause for self-gratulation. As the dividend statistics demonstrate, the decline has been more than balanced by the increase in the quantity of ore milled, together with the reduction in working costs. Even during the year 1908, the average expenditure has been reduced from 19s. 10d. to 17s. 3d. per ton milled. Though several mines appear to have reached the economic limit in this direction, with their total working costs in the region of 12s. to 13s. per ton, the Rand's average will certainly show a still further improvement, during the current year.

To whatever abuses the demand for reduced costs may have led in certain cases, where low-grade ore has been exploited in excess, it is at least certain that the policy has been appreciated to its full in European financial circles and

that the return of favor has been largely attributable to the evidence thus provided of the application of stringent economy. At the same time progress has been brightened by two or three important developments which strengthen the prospects of future success in areas yet beyond the productive sphere. In the Central Rand, for instance, the Village Deep has been improving in depth, and also the adjacent City Deep, in which two shafts have cut the reef at a depth exceeding 3000 ft. In this mine it is claimed that half a million tons of ore are developed, having an average recovery-value of about 40s. per ton, which is higher than the grade of ore in the neighboring mines nearer the outcrop. Again, in the Far East Rand basin, in a part hitherto untouched by shafts, the Brakpan mines cut the reef at a depth of 3695 ft., where it assayed 16 dwt. across a width of 81 inches.

The cloud of depression due to a shortage of unskilled labor, which hung over the Rand for two or three years after the war, has been gradually lifting. When the repatriation of the 50,000 imported Chinamen was decided upon, the prospects of the mines looked distressful. Fortunately, however, the tally of departures during the year has been exceeded by that of new arrivals from the Kraals of Portuguese territory and other parts of South Africa. The policy of increased economy enforced upon the mines has led to far higher efficiency in the ranks of the skilled white workers—especially since the strike of 1907—but the number of white men employed has been increased nevertheless by 2000 during the year. The totals for all the Transvaal gold mines for January and November 1908 are:

	Whites.	Kaffirs.	Chinese.
January 1908	17,522	133,515	33,849
November 1908	19,460	160,504	12,192
Difference	+1,938	+26,989	—21,657

The increase under the first head reflects in some measure the result of employing indigent white men upon work not requiring skill in order to relieve the acute distress experienced owing to retrenchments at Kimberley and other centres of employment at the beginning of the year. Although natives have been offering themselves in such unprecedented numbers, it must not be concluded that the industry is now proof against the restrictive influences of a shortage in future. The prospective needs of the field, estimated in the light of projects of expansion already planned and commenced, can only be satisfied if this increase be steadily maintained or, if an efficient small stoping drill is produced, capable of profitably displacing hand-labor in the narrower workings.

The most significant feature in a review of the past year has been the carrying into effect of numerous consolidations. The benefits of the policy of working in large units under a single management having been so clearly established, the mining houses have now decided to apply it wherever practicable. The scheme was initiated in a small way four or five years ago by the merging of the Crown Reef and the Pioneer, the Ferreira and the Worcester, and the Village Main Reef and the Wemmer. More recently, the following amalgamations were effected; Henry Nourse and Nourse Deep; Angelo Deep and South Angelo; West Rand Mines and Violet Consolidated; the South Rose Deep, South Geldenhuis Deep, Rand Victoria East, and Rand Victoria with the Simmer Deep; and the Jupiter and the Simmer West. This year the policy has been continued on a larger scale with the consolidation of the Village Deep and Turf mines; the Modderfontein Extension with surrounding properties; the Angelo, Driefontein, Cason, New Comet, and other holdings; the Kleinfontein Deep and Van Ryn Deep and lastly, in December, the Crown Reef, Crown Deep, Robinson Central Deep, Langlaagte Deep, Paarl Central, etc., into the world's greatest gold corporation, the Crown Mines, Ltd. This latter scheme, it is true, awaits confirmation by shareholders, but its favorable reception has removed all possibility of important opposition. With a capital of £1,000,000, in shares of 10s. each, the Crown Mines, Ltd., takes over four

producing mines with five mills now accounting for 1,600,000 tons of ore per annum, yielding £2,700,000 and earning from £1,400,000 to £1,500,000 in profits. As the life is estimated, on a basis of 1,800,000 tons milled per annum, at 50 years, the capacity of plant will undoubtedly be raised high above the present combined standard in course of time.

In Rand metallurgy, there have been several changes in practice, without affecting general principles. The erection of large electrical power-stations on the Rand is leading rapidly to the application of electricity to all the main units of power-consumption, and the new batteries in the East Rand are being driven by this means. The opposition of rival power-companies has been dispelled, so that during 1909 and 1910 electricity is likely to win its proper place, after long delay, as the chief prime-mover in modern Rand engineering. The Simmer Deep mill of 300 heads, electrically driven in units of 10, was completed in September. At this mill we see the general tendency of employing heavier stamps conspicuously illustrated. By the addition of compensating weights, a standard weight of 1650-1700 lb. is maintained. Tube-mills have increased in favor, the number at work in December being 120, as against 72 in January. By their extended use, the average stamp-duty on the Rand has been raised to 8 tons per 24 hours. Below the mill there have been no radical changes to record. The Adair Usher process for slime-treatment has been more extensively adopted, and 26 companies in the Transvaal were employing it at the close of the year, as compared with 11 at the beginning. In underground work, the most noteworthy feature has been the reduction of working costs, due principally to the improvement in personal efficiency. The standard of a good day's work has been steadily raised and enforced by the employment of more highly trained and qualified men in the minor positions of control. The stoped-drill competition at the close of 1907 from which the Gordon drill emerged an easy victor, appears, in one respect, to have borne no good results, for the Gordon, in its present form, has failed sorrowfully under the stern test of actual practice. Interruptions and expenses due to wear and tear have been extensive. On the other hand, the trials have taught a valuable lesson and have prompted the Government and the Chamber of Mines to arrange a more decisive competition to be carried out this year for prizes of £4000 and £1000, apart from awards to the operating miners. The former trial may be considered to have been a costly 'dress rehearsal,' but it has enabled the present committee to draw up a set of rules and conditions leaving no loop-hole for misinterpretation of results. The number of machine-drills employed in Rand mining is about 2400. Records have been established during the year in the East Rand. With hand labor, the No. 2 vertical shaft of the Brakpan mines, 42½ ft. by 9½ ft. in the clear, was sunk 204 ft., from 1690 to 1894 ft., in one calendar month, and the incline shaft at No. 1—19 ft. by 7 ft.—a distance of 223 ft. in a month, with six 3¼-in. machine-drills. In the Simmer Deep, a drive on the fifteenth level was carried 294 ft. in 61 consecutive shifts of 10 hr. each, one white man and six Chinese working each shift with three drills. The variation in the hardness of the 'blue' deep-level ground is not sufficient to make these records anything but surprisingly excellent.

The Transvaal Government early in March issued the report of the Mining Industry Commission, which investigated all questions of mining policy bearing on labor conditions. Under the chairmanship of F. H. P. Cresswell, the aim of this judicial commission was to force the mines to employ white labor, whether economically or not. The finding of the majority was expressed in a report so extreme in character that the Government, though favorable to the sentiments, found a pigeon-hole the most respectful grave to which it could be assigned with dignity. But if the deliberations of the Government's nominees were so absurdly barren of practical results, the same cannot be said of the labors of the ministers themselves. In the middle of the year the new gold law was drafted. Though not liberal enough in its provisions for outside prospecting and possibly too severe in its enforcement of work upon ground held

under claim licenses, this bill, which is now in operation, is not seriously detrimental to interests on the Rand. The Government thus proved its intention to ignore the cries of the political faddists and the outlook was brightened by the removal of fears of opposition between Johannesburg and Pretoria. After a long period of instability, the Rand appears to have been re-established during the past year upon an improved and settled basis.

NEW YORK.

New Chlorination Method.—Standard Oil and Yukon Gold.—Guggenheim's Statement.—Copper Situation.

Mining men in New York are taking great interest in the Baker-Burwell dry chlorination plant recently erected in Montana to treat the Elkhorn tailing. Fuller details of the process are now available. The crushed ore, which may contain any combination of metals, is treated with chlorine gas while subjected to a temperature sufficiently high to cause the chlorine to combine with metals to produce volatile chlorides or soluble proto-chlorides. The process is carried out in revolving porcelain-lined tubes, or flint-mills having hollow trunnions and enclosed in a chamber of brick or boiler-iron, to facilitate heating the ore. The heating chamber is fired by gaseous fuel. Chlorine gas is fed to the tube-mill through the trunnions, which are also porcelain-lined. In the treatment of ores containing gold, silver, and iron sulphides, the tube-mill is charged to about one-third its capacity with ore crushed to about 50-mesh. The charging-doors of the mill, and its enclosing chamber, are sealed, and the mill is revolved. The ore is then heated to a temperature of about 150° C. Chlorine gas generated electrically from sodium chloride solutions is introduced into this mill and allowed to combine with the metals and with the sulphide. The sulphur and chlorine form sulphur mono-chloride, S_2Cl_2 , which is withdrawn from the mill and condensed. The base metals in the ore are converted to proto-chlorides. When the formation of sulphur chloride ceases, which is shown when chlorine gas begins to pass to the condenser, the chlorine supply-valve is closed, and the ore is spread on a cooling-floor. When cooled, the ore is treated with water to dissolve the soluble chlorides. The free gold in the ore is saved by amalgamation, cyanide solution, or by wet chlorination.

It is persistently rumored in Wall Street that the Standard Oil people have acquired a controlling interest in the Guggenheim mining properties in Alaska, and that some large financial schemes will shortly be arranged preparatory to listing on the New York Exchange, where they are to be manipulated on the lines so profitably followed in the cases of the United States Steel and Amalgamated companies. President S. R. Guggenheim has issued a statement to the stockholders of the Yukon Gold Mining Co. regarding the present conditions of the property and future prospects. The gold in the developed ground is estimated at \$40,000,000. The net earnings to December 31, 1908, are about \$550,000. For 1909 the earnings will probably exceed \$1,000,000. "I have no doubt," says President Guggenheim, "that the directors will authorize the commencement of dividends during the year, probably in the second quarter; but before deciding definitely as to the date and rate they deem it prudent to wait until the coming season's operations have sufficiently advanced to enable them to more accurately estimate the probable earnings for 1909. Early in 1906 work was begun upon a water system (now completed) which will insure to the Klondike a continuous water supply for all time. This involved the diversion of Tombstone river (the right fork of the Twelve-Mile river), carrying it 62 miles by flume, ditch, and pipe-lines through a country that was an absolute wilderness when the company's engineers went there. The water is carried across the wide Klondike valley in an inverted siphon, which for length, size, and pressure involved is not equaled in the world. In addition to these primary physical achievements," says President Guggenheim, "a huge dam has been built at the head of Bonanza creek to conserve the waters

of the Upper Bonanza water-shed for the use of the company's Bonanza and Eldorado creek properties. Seven giant dredges have been completed, and their operation has demonstrated the entire success of this method of mining as applied to the gravels of the Yukon. In 1910 we expect to show a production which will make the Yukon Gold company take rank as one of the largest gold mines in the world."

The statement intimates that the Guggenheim Exploration Co. still holds a controlling interest in the company. The controllers of the Exploration company are not disclosed.

There has lately been a large amount of pessimistic talk regarding the outlook for copper mining, and copper stocks have been heavy on all the stock exchanges. All kinds of wild stories are being scattered by the news bureaus regarding the piling up of copper stocks owing to the overproduction of copper. A prominent manufacturer, who is a large user of copper, is reported having stated that electrical plants are at present consuming copper at the rate of about 50% of normal, and the present consumption of copper in the United States is about 65% of normal. North American mines are producing the metal at the rate of about 1,350,000,000 lb. per year. Consequently about 35% of the present production is going into storage. It will doubtless be a long time, this manufacturer believes, before the price of copper advances. It appears that these pessimistic statements are being issued in the interests of the copper trust. Copper production at present is not as large as is believed.

BUTTE, MONTANA.

Butte & Ely Option.—Minnesota Mine.—Legalizing Consolidation.—Ponderay Smelter.—East Butte Company.

The Butte & Ely Copper Co.'s property is under option to the Cole-Ryan people. It is optioned in the name of T. M. Hodgins for \$1.90 per share of the stock. The property is situated between the Giroux, recently acquired by the Cole-Ryan interests, and the Nevada Consolidated, controlled by the Guggenheims. It is said that the best ore found in the Nevada Consolidated ground is near the end line of the Butte & Ely. The latter owns a valuable water right, while the Giroux has no water. The small smelting plant, which was erected by the Giroux and which was afterward destroyed by fire, was to have been operated on water pumped from the mine. The Butte & Ely owns 12 patented claims of 210 acres. The company is capitalized for 500,000 shares at \$5 par, and about 257,000 shares are outstanding. The option at \$1.90 per share includes the treasury stock and the majority of the stock outstanding. It will expire March 1. The stockholders have elected the following officers and directors: R. M. Hodgins, president; B. E. Calkins, vice-president; A. L. Langley, treasurer; T. B. Moore and J. C. Adams. W. E. Wright is secretary. The company has done some development work, but stopped at the beginning of the financial depression.

The litigation between the Butte & Superior Copper Co. and John McAlpine, a stock subscriber, has been terminated, Mr. McAlpine abandoning his fight and paying the notes he had given in payment of stock subscriptions several years ago. He refused payment on the allegation that the value and condition of the property had been misrepresented to him. McAlpine, like many others, was let in on 'the ground floor', paying about \$3.50 per share for the stock on rosy and misleading representations and promises of big advances and profits.

There will apparently be no litigation between the United States Government and the Amalgamated Copper Co. over the Washoe smelter-smoke problem. The company and the Government are now working together in an endeavor to find means for minimizing damage from the arsenic in the smoke.

What big things may be done in mine-promotion without

capital is shown by a statement of the secretary of the Calumet-Corbin Mining Co., a concern organized in Michigan to exploit the old Minnesota mine at Wickes, Mont. The promoters get the property for \$100,000, but have been required to pay only \$2000 down, no other payment being due until the first of next October, when the company is to pay \$15,000 more. Thereafter the remainder of the payments extend over a period of 20 months. Meanwhile the public is asked to buy the stock on the Eastern curbs. Under the option the company has the right to extract and ship ore while developing the property, but 20% of the net smelter returns must be applied on the purchase price where the ore value does not exceed \$45 per ton, and 25% where the value exceeds \$45. The original owners of the option on the property receive 26,000 shares of stock, \$1 paid, which is held in escrow in the name of three trustees, which stock will be released only at the discretion of the board of directors. The Calumet-Corbin Co. was originated by several Butte men, who secured the option on the Minnesota.

A bill is before the Montana State Legislature providing that a corporation may own stock in another corporation, and it will undoubtedly become a law. It was introduced in the interest of the Amalgamated Copper Company.

Wilbur D. Greenough is quoted as saying that the Greenough brothers do not intend to give up their attempts to make a success of the Panhandle smelter at Ponderay, the property of the Idaho Smelting & Refining Co., in which they own a controlling interest. He says they have spent \$55,000 in improvements. The smelting company has an indebtedness of \$290,000 and the smelter is being operated at a loss. The company has authorized an issue of \$400,000 worth of bonds, but only \$100,000 have been issued. For some time the smelting company has had agents in the field trying to secure business, and the independent miners of Butte and other districts of Montana have been urged to patronize the smelter and make it possible for an independent plant to be maintained. The Ponderay smelter, after a long shutdown, was started up at the instance of the Montana Mine Owners' Association as a competitor of the smelter trust and the Amalgamated Co., which were accused of discrimination against the independent miners. It now appears that the latter are not patronizing the smelter as they should.

The East Butte Mining Co.'s concentrator will be completed and ready for operation shortly after February 1, after which, it is expected, the immense body of low-grade ore on the upper levels of the mine can be mined and handled at a profit. Some high-grade ore is being mined on the 400-ft. level, and the long cross-cut being driven south from the shaft at the 900-ft. level has cut three or four veins, several of which are of good size and bearing good ore. Driving is being done on the larger veins, the orebody in which assays 9% copper. The Amalgamated Copper Co. is mining on the same veins, both on the east and west of the East Butte ground. Complete harmony and a perfect understanding exist between the East Butte and its neighbors. An annual report made by the Raven Mining Co. shows that it has an indebtedness of \$72,000, which explains the necessity of the recent appeal to stockholders that they subscribe to a block of treasury stock at \$1 per share. The stock is quoted on the market at 75 cents.

At the annual meeting of the Butte-Montana Mining Co. it developed that control of the company was held by Pittsburg men, who favor a plan to increase the par value of the stock from \$1 to \$10 per share and to increase the capitalization about half a million dollars. The present capital consists of 1,000,000 shares. The company needs funds for development on the Alex Scott mine and to build a concentrator. The mine has a large quantity of low-grade ore in sight and could be made to pay. Some smelting ore is now being shipped. There is considerable opposition in Butte among the small shareholders to the new plan. The new directors elected are: J. P. Browne and W. H. Lindsay of Butte; J. G. Bennett, John B. Chapman, W. B. Chapman, and M. K. McMillan, of Pittsburg; R. A. Kerr of Duluth.

LONDON.

Refractory Material Standardization. — Institute of Metals. — Briseis Company's Expansion. — Cornish Mines.

The study of refractory materials has been taken up systematically by a body called the Committee for the Standardization of Refractory Materials. The secretary is Dr. J. W. Mellor, of Stoke on Trent, Staffordshire. The idea was originated a year ago by the English Ceramic Society and soon extended to the Institute of Gas Engineers. Strong support also came from the Iron & Steel Institute, and later on, the newly formed Institute of Metals joined the movement. A meeting was held on January 4, and preliminary arrangements were made for carrying out the work. The chairman of the committee is J. E. Stead, of Middlesbrough, and the vice chairman is J. H. Darby, of Brymbo, two gentlemen who are well known in metallurgical circles. The objects of the committee are to arrange and classify the various refractory materials, fireclays, ganister, magnesite, chromite, etc.; to arrange standard specifications for the raw materials and for manufactured products; to consider the possibility of arranging for uniformity in stock and standard sizes; and to arrange standard methods of testing and analysis. The procedure to be adopted is that individual members of the committee shall bring the matter before the particular institutions which they represent and obtain information and suggestions. In this way the committee will be divided into subcommittees which will conduct independent investigations. These will consist of the Ceramic Society division, one representing chemical and electrical work, another for glass, for gas engineers, pottery, metallurgy, and for general manufactures. The committee invites opinions on the following lines: (1) Materials at present in use, general information, analysis, etc.; (2) conditions of use, nature of furnace operations, temperature, and whether the temperature is continuous or intermittent; (3) criticism of materials at present in use; and (4) suggestions as to improvements both in material and sizes and patterns available; the Ceramic Society division will deal with, (1) the definition of refractoriness; (2) grades of materials, based on, (a) refractoriness; (b) class of material, whether aluminous, as clay and bauxite; silicious, as ganister and silica; and special, as magnesite, etc.; (3) the examination of raw materials, chemical analysis, standard method, of determining refractoriness, mechanical analysis, and behavior at various temperatures, shrinkage, porosity, plasticity. The manufacturer's division will prepare suggestions as to the elimination of odd and little-used sizes and shapes, standard sizes and shapes, deviation from specified dimensions in special sizes and as to the grading of clays as proposed by the English Ceramic Society. There is no doubt that the studies and information brought together by this committee will be helpful to metallurgists, and their co-operation is solicited.

The Institute of Metals held a meeting in London this week, when a preliminary report of progress was made. So far 273 members have joined, and the membership is spreading. Offices have been taken at Caxton House, Westminster, close to those of the Civil Engineers, Mechanical Engineers, and the Iron & Steel Institute. Arrangements are being made for establishing a journal and transactions. At the meeting this week Sir Gerald Muntz read a paper on research work which is of value to the metallurgist, and he appealed strongly to manufacturers and producers to communicate their knowledge and to abandon the old policy of secrecy. In fact it was a counterpart to the like appeal by James Douglas, and coming from a man who depends for his living on his special knowledge, it is all the more noteworthy. He showed that a great deal of knowledge runs to waste through secrecy, through the jealous fear of teaching something to a trade opponent which he has probably discovered also, whereas if the two frankly discussed the subject, each would give the other valuable hints which would make their total knowledge greater. With equal knowledge, it will still be the best man who

will best apply it. If men have courage and confidence in themselves they need not hesitate to exchange information. Altogether, Sir Gerald's address was a frank condemnation of secrecy, but to what extent his confrères will meet his pleading is not quite certain. English metallurgists have never been communicative owing to their not being the owners of resources of raw materials.

The directors of the Briseis Tin Mines Ltd. have taken an interesting step by acquiring gold-gravel properties in the colony of Victoria. The company has for some years been working the tin-gravel mines of that name in Tasmania, and as the extent of the property is almost exactly known and the life of the mine is nearing its end, efforts have been made to acquire additional property. The Ringarooma tin property was purchased some time ago, and it should begin producing in about a year. In developing it, the engineers have decided to remove the overburden first,

Eastern Australia.

and so prevent a repetition of the series of mishaps that occurred at the Briseis by the valueless overburden occasionally falling in and interfering with operations. Already over 500,000 yd. of overburden have been removed at Ringarooma. Further prospecting has been conducted in Tasmania for tin, and probably when the Briseis water-supply becomes available on the final exhaustion of the mine, other properties not far off will be acquired. In the meantime the decision of the company to exploit gold-gravels in Victoria is interesting. These properties are being acquired from C. D. Wallace, a pioneer gravel operator, who has worked them by sluicing for some time. They are situated on Yackandandah and Sandy creeks, and extend over 2000 acres. The gravel is not encumbered by boulders or trees, and is comparatively easy to work. An area of 440 acres has been thoroughly prospected by the Briseis company's consulting engineers, Lake & Currie, and their general manager, C. Lindesay Clark, has made confirmatory examinations, and they find that on this area there is 19,000,000 cu. yd. of gravel that will yield 3 to 5c. per yard profit, taking 4c. as the cost of operation. Mr. Wallace will receive altogether £60,000, of which £15,000 will be paid in cash in three yearly instalments, and the remainder will be paid in the form of 20% of the yearly profits. It is expected that all the payments to Mr. Wallace will be made out of revenue, so that no new issue of shares will be necessary, but in view of the extension of the company's operations the name

of the company is to be changed to the Briseis Tin & General Mining Co. Limited.

The Wheal Kitty was the only mine in Cornwall to declare a dividend during 1908, with the exception of the small interim-dividend paid by Dolcoath in the early part of the year. The report of Wheal Kitty for the second half of 1908 shows equally good results, for a profit of £2204 has been made, a figure practically the same as during the first half of the year. As before, only £825 is being distributed as dividend, which is at the rate of $7\frac{1}{2}\%$ per annum, and the remainder placed to the funds for sinking the Sara shaft another 540 ft. and equipping it, and for providing a modern dressing plant. About £10,000 is required for carrying out this work, and some of the additional capital has been subscribed. It is a bad time for raising money in Cornwall, and if the whole of the money is not forthcoming, it may be deemed necessary to continue putting aside a large proportion of the profits. During the second half of the year the mine produced 5541 tons of ore, yielding $119\frac{3}{4}\%$ tons of concentrate which sold for £10,152, or an average of £84 per ton.

Discussion is active in Cornwall over the lack of facilities given by bankers to mining companies and to other commercial enterprises in regard to granting loans. In the old days the Cornish banks were in private hands, and they were always ready to finance promising propositions, for the owners had intimate knowledge of their neighbor's standing and character, and indeed took large interest in local enterprises. Nowadays these banks have been absorbed by gigantic institutions in London which work by fixed rules and regulations, and cannot judge each case on its merits. Mining is therefore too risky a business for them. On the other hand, many of the mines here adopted the limited liability principle, which provides little or no security to the creditor. In the old days of the cost-book system, each individual was practically liable for the debts of the company, so that the bankers had a personal security for their loans. These two facts explain the reason why banks give so few facilities to mines nowadays.

NOME, ALASKA.

Labor Conditions.—Large Dredging Enterprise.—Difficulties of Mining on Seward Peninsula.—Mail Service.

The excitable stage in labor conditions, foreshadowed by the recent order of the American Federation of Labor and Western Federation of Miners of a \$4 per day wage-scale, has passed. Only one camp in the Nome district is now a recognized union camp, namely, Waskey & Crabtree's. The Pioneer company has 12 hoists operating at Little Creek, all working non-union men, but nearly all the other operators have closed down rather than pay the union schedule. This prolonged resistance to the edict of the unions has suggested a solution of the problem. The local chapter of the Western Federation of Miners is proving itself thrifty and resourceful, and while the small operators are generally denied credit for supplies by the local merchants until the spring clean-up, the union is backing a syndicate of its own for obtaining supplies and to carry on the business of contracting and leasing mines. These operators pay cash for supplies, and they are working entirely for themselves, having no need to trust anyone else for the payment of their time-checks in the spring. A repetition of the \$380,000 in unpaid time-checks floated in the Tanana district last year, seems to have been avoided. All business in Nome is on a cash basis this winter. Operators outside the W. F. M. Syndicate must pay cash for wages monthly; the merchants' combine demands cash for supplies and has started a blacklist of delinquents; the banks are refusing to loan money on dumps, on any pretext; and thus the merchants and banks get all the loose money anyhow, while the operators who have no cash with which to conduct operations must quit and give up to the Syndicate which is at work everywhere, while development and production from the mines is not altogether stopped, but only temporarily retarded.

Nome, in a business sense, as compared with former win-

ters, is as dead as the proverbial door-nail. As stated, the banks and merchants have turned their backs on all operators who are without funds to carry on winter work and many of them must quit. These conditions are the result of finesse in trade combination, which in a measure will retard the development of the country, but in the outcome prepares it for favorable exploitation by capitalists and those who are interested in the trust. It is only a question of who is to control in a mercenary sense.

Claims well situated and many that have been known as steady producers, can now readily be purchased on terms favorable to the buyers. An immense area of placer ground has been optioned by New York promoters; this lies west of Snake river on the tundra toward Penny river. It is said to comprise 60 association claims of 160 acres each, which are to be worked by dredges of the Bucyrus type, with thawing plants capable of overcoming obstacles due to frozen ground. The deal is said to comprise all of the claims exploited by J. U. Picard in 1903, '04, and '05. One of the lessons taught investors by the failure of Picard's company was the necessity for mining syndicates to provide capital enough to supply their own outfits, direct from the States, to insure success. Investors who do not heed this injunction are courting disaster and disappointment.

Open-Cut Mining on No. 3½ Above Ophir.

Under existing conditions, the small operator, with limited capital, must pay exorbitant transportation rate to a combine which controls the shipping, lighterage, fuel, and food supplies of Seward Peninsula. At Seattle he is told that he "can get everything he wants in Nome at Seattle prices." In summer coal costs \$15 per ton; in winter \$20 to \$35 per ton, and everything else is 'upward.' These facts he ascertains too late, for he has formed his company and provided himself with capital based on this false information. Arrived in Nome, he finds he must have more funds. The stockholders are scattered, and it is necessary to return to the States to present matters as they actually exist. The first season is thus lost. The investor in Alaskan industries must prepare well for all emergencies. Last winter many investors found their drafts repudiated; operators encountered the same conditions. These circumstances were unlooked for, and perhaps may not occur again, but they represent difficulties for which investors must be prepared. Nome business houses are the stockholders of the banks; they have set out to develop a cash trade; and the banks, accordingly, should have a large amount on hand to carry the work of this vast country. They are not carrying anybody, and investors thus are made to understand, that, even though transportation rates are high, it is far safer for them to bring in their own supplies, and whatever cash they need for all the emergencies that go to make up the rigors of an arctic winter, where even Uncle Sam requires six to ten weeks to transport currency wherewith to pay off his soldiers. Mail conditions in winter are improving and will continue to improve, a relay dog-team service being already in contemplation, which will trans-

port mail from Nome to Valdez in 12 to 14 days.

When railroads provide competition, and cheapen the price of living and supplies, then will ensue an era of prosperity in Alaska for the poor miner as well as for the highly financed operators. Until then only cautious and economical mining will insure success.

KALGOORLIE, WESTERN AUSTRALIA.

Total Gold Output.—Strikers Arrested.—King v. Ivanhoe.—Discoveries in Lake View Consols.—Dump Treatment at Oroya-Brownhill.

During the past eleven months the gold yield from all mines in the State reached a total of \$32,000,000, that was \$700,000 below the same period of 1907. The dividends paid this year were \$6,500,000 against \$7,500,000. Estimating the gold yield for December at \$2,900,000, we have \$34,900,000 for 1908; and as dividends for this month amount to \$95,000 this total is \$7,595,000. The grand totals from 1886 to 1909 are \$420,000,000 in gold, and \$93,900,000 paid in dividends. The November returns were as under:

Mine.	Tons.	Yield.	Profit.	Dividend.
Associated	10,664	\$111,000	\$ 36,000	\$125,000
Associated Northern				
Blocks	3,660	38,000	13,000
Golden Horseshoe	23,442	270,000	100,000

Sons of Gwalia South.	1,850	20,000

*Shut down part of month on account of wood strike in the Day Dawn district.

The second wood strike is at an end so far as Kalgoorlie is concerned, the leaders in the trouble being arrested for intimidation and sentenced to short terms of imprisonment. All is quiet again, but the presence of so many foreigners among the woodcutters is most undesirable.

The King v. Ivanhoe case, mentioned in one of my letters, has advanced another stage. The position to date is as follows: In the original case before the Supreme court of W. A., King got a verdict of \$18,000 and costs. The Ivanhoe Co. appealed to the Full Court, which decided that the damages were excessive. The plaintiff then appealed to the High Court of Australia. This Court also considered that the damages were too high, thereby upholding the Full Court, and ordered a new trial. This was commenced before the Supreme Court a fortnight ago, and the case looked as if it were coming to a speedy termination, when two jurymen were arrested for trying to make a deal with King in order to influence the rest of the jury in his favor. It was through King that the jurymen were arrested, and it may be said that both parties in the case are entirely innocent. However, the judge dismissed the jury, and hung up the case till March next. The accused men are to stand their trial shortly. What is to be gained by all this litigation is hard to understand, but the plaintiff apparently is determined to fight to the bitter end.

During November there was a good development at 1900 ft. in the Lake View Consols. This mine has not been looking too promising of late, and the profits have been small, and as a result of this strike future prospects will be much improved. The extraordinarily high returns from a bonanza between the 300 and 400-ft. levels in this mine between May and November, 1899, may be remembered. The oxidized ore

was rich, and the telluride ore shipped to the smelters was wonderful. The following are the returns for the months above mentioned:

Month.	Tons.	Returns.
May	8,450	\$680,000
June	8,440	620,000
July	8,010	618,000
August	6,620	644,000
September	4,956	618,000
October	6,290	618,000
November	4,406	245,000

During this boom-time \$5 shares rose to \$150; but when the bonanza dropped out, they fell to \$50 in a few days. Then came a series of changes in management until Bewick, Moreing & Co. assumed control, although this was a fearful scandal—the manager in 1899 cabling to his directors that he could keep up this large output for 2 years—no enquiry was held, as in the cases of the Perseverance and the Boulder Deep Levels' scandals of 1904, when the Government stepped in. When this present development was announced in the Lake View Consols, scrip mounted pretty smartly, but has fallen back to a more reasonable figure. This company has evidently a serious problem in the treatment of its old dumps by the Cassel process. From a report published, it appears that the assay before has been \$2.90 per ton, and after treatment \$1.34 per ton, giving an extraction of about 54%. As long as the soluble gold is all washed out, it is doubtful whether it would pay to go in for a longer treatment of this stuff. The new Cassel plant on the Oroya-Brownhill, to treat upward of 26,000 tons of old dump monthly has started work. The slime is trucked to a small hopper, elevated by belt conveyor to 2 vortex-mixers in series, agitated in 10 vats, and treated in 2 Cassel tanks, each containing about 25 frames. The tanks are filled and emptied by an 8-inch centrifugal pump, and the treated slime, when blown off the frames, drops into large mixers, and is pumped away to a dam. All the present mill tailing is also pumped away, the belt conveyors and boom-distributor being dismantled after making one of the finest dumps one would wish to see.

During the past month the mines used 30,398,000 gal. of water. Having had many days over 90, and several up to 108°F. in the shade, and several huge dust-storms, the consumption of water by mines and residents has risen considerably. The Water-Scheme officials are much worried over the corrosion of the steel pipes. External rust can be checked, but the internal corrosion is going to cost a lot of money. The water does this, in spite of the fact that analyses indicate nothing injurious. Much experimenting is now in progress.

The crank-shaft of the main hoist at the Great Boulder main shaft broke recently. At the point of fracture the shaft is about 13 in. diam. Repairs will be carried out in Australia, instead of sending to England. This hoist was made by Robey, of Lincoln, and is capable of hoisting 3 tons from a depth of 3000 ft. in 3 minutes. The new vertical hoist at the Edwards' shaft is now being erected. The new steel head-gear is practically finished, and the 'crackers' are now being put in. There is a size T Hadfield's gyratory for first breaking, followed by 2 of size R, and from these the broken ore will be taken to the mill-bins by belt-conveyor. The Ridgway vacuum machines are treating the regular mill pulp, the re-treatment of old dumps apparently being suspended indefinitely.

While not being in connection with mining, it may be of interest to mention that the pearling industry of the north-west of this State has suffered another severe shock. Last year a cyclone—or what is known locally as a 'cock-eye'—struck the various fleets, drowning a great number of whites and natives, besides inflicting about \$200,000 damage. Last week another 'blow' occurred, and although the loss of life and the damage is not ascertainable at this writing, it will be considerable. The pearl shell gathered this year—10 months—is valued at \$720,000, and the total value of shell and pearls since 1897 is about \$9,750,000.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Storage batteries cost, erected, from \$75 to \$90 per kilowatt.

Colombia has adopted the gold standard, making the dollar the monetary unit.

The average price of carbon used in diamond drilling, during 1908, was about \$75 per carat.

Ten inches of snowfall are equal to one inch of rain. This is the ratio used by the United States Weather Bureau in computing precipitation from snow.

Alcohol and gasoline engines when running under the most advantageous conditions for each, will consume equal volumes of the fuel for which they are designed.

Gold is valued in England, unless otherwise stated, on the basis of the British standard, which is 916²/₃ fine. The mint price per ounce is £3 17s. 10¹/₂d., equal to \$18.9491. The mint price for gold 1000 fine is \$20.671.

Oxygen equivalent, in relation to flue gases, is a term which expresses the sum of the volumes of oxygen, carbon dioxide, and one half of the carbon monoxide, calculated to its equivalent in oxygen as a means of comparison.

Manganese oxides and hydroxides are insoluble in water. They are soluble in warm hydrochloric acid, forming manganous chloride. The higher oxides in dissolving in HCl evolve chlorine, which is the basis of the old commercial method of preparing that gas.

Losses of gold in melting under the most favorable conditions would certainly be those recognized as within attainable limits at the United States Mint. Records kept at the San Francisco Mint show the following losses, stated in percentages: on bars, 0.00116; on dust, 0.03392; on 'retort', 0.05572; on un-retorted amalgam, 0.64904.

Tungsten is used chiefly for hardening steel. For that purpose the consumption in 1907 was 5791 tons, but in 1908 it was greatly reduced. The consumption for making incandescent electric lamps is utterly insignificant. The annual output of such lamps in this country is about 10 million, and one ton of 70% tungsten ore will make 18 million lamps.

Zinc for gold-precipitation in the cyanide process should be as free as possible from iron. The presence of iron hastens corrosion, increasing the 'short zinc', and incidentally the consumption of both zinc and cyanide. The cause of this is open to some doubt. Evidently an internal zinc-iron couple is formed, but the iron is present in the zinc most probably as a mechanically included oxide. The action observed may be facilitated by the presence of carbon in the

zinc. The subject is worthy of more detailed investigation than it has received. It is undoubtedly true that the deleterious effect is reduced by maintenance of a proper alkalinity in the solutions.

Grouting of cracks in foundations and walls should be done under pressure. This is accomplished by discharging the contents of a receiver filled with grout (which is a mixture of cement, fine sand, and water, of the consistence of cream) under air pressure. For this purpose an air pressure of from 80 to 100 lb. per square inch should be used. The edge of the crack should be pointed up, and allowed to set before filling with grout.

The Red Jacket shaft in Michigan is the deepest in the world, and has the most powerful winding machinery. The shaft is a mile deep, and the engines wind 10-ton cars of ore 1 mile at the rate of 40 miles per hour, or from bottom to top in 90 seconds. The shaft is so deep that the effect of the earth's revolution can be detected, for an object dropped always strikes the east side of the shaft before reaching the bottom.

Caissons have not been applied to shaft-sinking in placer mining, so far as we are aware. The process would be costly, and were there reason for sinking a shaft through watery gravels to reach bedrock-gold which could be worked subsequently by mining from the bottom of the shaft, the freezing process would apparently be the more economical. We cannot, however, conceive conditions in placer ground where material could be mined that necessitated such means for its approach.

Piping in steel ingots may be overcome to a large extent in various ways. Harmet has applied compression, the metal in the mold being forced toward the narrow end so as to induce radial pressure. The compression begins while the metal is still molten. Sauveur introduced a so-called continuous mold, the metal filling all the sections of the mold and covering the partitions. The piping will occur mainly in that portion of the mass above the partitions, and can be cut off. Another simple method to reduce the evil of piping is to cast the ingots with the small end down. The extra pressure prevents deep piping in an ingot so cast.

Diamonds at the Premier mine, near Pretoria, Transvaal, are found in 'pipes' consisting of a highly altered material largely converted into serpentine, and carrying fragments of country rock. These fragments have been brought up from deeply seated formations. Among the most common minerals other than serpentine are olivine, enstatite, hypersthene, chrome-diopside, garnet, ilmenite, biotite, vaalite, magnetite, epidote, apatite, calcite, and zeolites. Tourmaline, corundum, cyanite, barite, and rutile are also present. The original rock is supposed to have been peridotite. The outcrop is yellow to brown, but in depth it has a blue color, similar to the diamond-bearing 'blue-ground' of Kimberley. The volcanic pipe has traversed Paleozoic rocks.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Slickensides.

The Editor:

Sir—In many mines the vein or lode lies in a fault-fissure and the walls of the fissure are slickensided showing a smooth or polished surface with striations, grooves, or fluting. The California earthquake of 1906 was due to a fault-movement, which has raised the question of the prevailing direction of fault-movements in general. To get information bearing on this question I desire to assemble observations on the orientation of slickenside striations. To make observations in the mine, it is necessary to note the strike and dip of the wall upon which the striations appear, measuring the dip from the horizontal, and observe the angle of inclination of the striations in the plane of the wall, noting which way they are inclined. In some cases the slickensides occur on slips within the vein rather than on the walls of the fissure. There may be also more than one system of striations. Mining men can greatly aid me in this investigation and any information will be gratefully appreciated.

ANDREW C. LAWSON,

Chairman State Earthquake
University of California, Investigation Commission.

[Mining engineers, geologists, managers, superintendents, miners, and prospectors are urged to aid Professor Lawson in this useful enquiry.—EDITOR.]

The Engineer as a Financier.

The Editor:

Sir—In entering into the discussion you invite on the ethical obligations of the professional mining engineer and his rôle as a financier, I wish to avoid sharing in any confusion that may arise from the use of the word financier in its double meaning, of one skilled in commerce and finance, and of one whose occupation is the obtaining and using of other people's money for the purpose of carrying on operations he recommends as profitable. This latter I will call a promoter, namely, one who finds the ocean and a compass for other people's ships.

We have recently been informed by the president of the American Institute of Mining Engineers that the functions of the mining engineer have expanded because this is an era of expansion. This is a *non sequitur*. Ours is indeed an era of expansion in respect to expanding fields of enterprise, and chiefly so because of enormously increasing knowledge. To be especially useful the individual must content himself with the accumulation, co-ordination, and application of special knowledge concerning only small portions of the entire fields open to enterprise. For

the world this is an era of expansion—for the individual it is an era of specialization.

I do not agree with Mr. Hammond that an engineer, having recommended the purchase of a mining property, incurs any moral or other responsibility for its subsequent efficient management, unless he accepts its management; nor do I think he is in any way bound to accept that management. Moreover, though admirably qualified to act as consulting engineer, he may be totally unacceptable as a manager for want of commercial experience and knowledge of organization. It is not a function of the commercial man, or of the promoter to be an engineer; even though this be an era of expansion. A professional man is one who, having special knowledge of a certain field, declares to the world that his vocation is to apply that knowledge to the uses of others and not to his own purposes except as to his fee or stipulated remuneration. Therefore, when the professional engineer offers to his clients his knowledge, services, and advice, his disinterestedness in everything but his fee is implied, and it is upon this guarantee of professional conduct that he invokes the confidence and respect of the public.

He must not only be disinterested and free from bias; but he must not do things that expose him to temptation or permit himself to be brought into situations where his own personal interests will conflict with the interests of his client. The ethics of a profession are not only the few rules of scrupulous conduct that can be written into the governing laws of a professional body, but are also the unwritten general precepts of conduct observed by honorable gentlemen—principles that must be innate or inbred if there is to be any hope of their faithful observance.

The professional man occupies toward his client the position of an employee or agent to a principal. It is, as far as I know, a universal law that that which an employee gains (other than his remuneration) by virtue of his employment belongs to the employer. Any retention of these gains, such as secret commissions, is in some countries a criminal offence and would, if discovered, lead to the imprisonment of the guilty employee or agent; and in all countries, I imagine the dishonest gain could by law be recovered by the proper owner. The acceptance of secret commissions is morally degrading, and if known disgraceful.

The contingent fee has always been abhorrent in the professions, and I would expect that if ever there should be formed in this country an association of mining engineers having a professional basis, one of its canons would be to forbid the vicious contingent fee. For a lawyer to procure his fee out of the money he may be able to collect by a damage suit, or for a professional mining engineer out of the proceeds of the successful sale of a mine, is unprofessional. This is work for the 'outsider'. The disloyal employee who does not serve his employer in good faith, with ordinary care and diligence, and with all the skill he possesses, not only breaks an obligation imposed upon him by law, but atrophies his moral fibre to his own serious injury. I believe that the

making of a report for the seller of a mine is undesirable work for a mining engineer, and that such work should be accepted with caution and precaution. The engineer in such a case should protect himself against the misuse of his reports, and against certain very easy mistakes that can be made in the copying of reports, by which a decimal point may be displaced and \$2 assays, for example, may appear as \$20, or veins of 2 ft. may be stated as of 20 ft., etc. It is a pity that this work should be undesirable, because intrinsically it would appear to be useful employment for the young engineer. But this is a question, as Mr. Hammond wisely observes, not of professional ethics, but of personal wisdom. I can conceive that a professional society might permit such work if certain precautions could be observed, but I have not been able to think of any that usually would be acceptable to the seller of the mine.

The professions, as an outcome of ancient experience, have formulated certain rules, and have inculcated the strict observance by its members of the highest principles of honor and good faith, for the triple purpose of raising and holding the professions high in public esteem, for the protection of the public, and for the protection of their members in professional relations with each other and with their clients. The private engineer with a single or a few special employers may permit his employers to judge for him whether his associations are dangerous to their interests.

The professional engineer has not the privilege of shifting this responsibility onto the shoulders of his employers, and when he assumes the garb and gown and the dignity and degree, of the professional man, he avows not only that he *is* honorable, but that he will keep himself entirely aloof from allurements that would be considered by worldly people as likely to lead him astray.

LEWIS T. WRIGHT.

San Francisco, January 28.

Tailing-Wheel v. Pump.

The Editor:

Sir—During the past few months several communications have appeared in your journal on the subject of tailing-wheels and pumps, for handling tailing and slime, for both concentrating and cyanide mills. Some of these letters have dealt with the matter at length, but I believe none of the writers has mentioned the proposal made a short time since, on the Witwatersrand, to replace the tailing-wheel by a modification of the air-lift pump.

In 1907 an elaborate series of tests was carried out on a full working scale by Messrs. Henderson and Wilson at the Angelo and Cason cyanide mills, each of 200 stamps. A complete account is given in an article published in *The Engineer* (London) of January 10, 1908. These tests were made, not in the interest of any manufacturer of mining plant, but under the auspices of the company, in the endeavor to find some practicable means of avoiding the use of either tailing-wheels or centrifugal pumps. In raising both slime and sand, the results show a satis-

factory degree of economy in consumption of power, and, as the apparatus is extremely simple, with no moving parts, the wear and tear is small. The scouring action of coarse sand, in the air-lift column or delivery-pipe, may readily be prevented by a wooden lining. Moreover, it was found by the engineer in charge of the tests that if the thickness of this lining be varied, being made thickest at the bottom, the roughly tapering cross-section of the delivery-pipe produced a materially higher efficiency than when the pipe was of uniform section throughout. Efficiencies as high as 36% were thus obtained from delivery-pipes measuring 14 in. diam. at the bottom and increasing to 16 in. at the top. I may add that similar efficiencies were secured from tests made in 1906, at Wandsworth, England, on an air-lift pump with tapering delivery-pipe.

ROBERT PEELE.

School of Mines, Columbia University, January 14.

Almarin B. Paul.

The Editor:

Sir—In your issue of January 16 I see a notice, a too brief notice, of Almarin B. Paul, one of the most notable figures in the early mining history of the Pacific Coast, and the inventor of what was long known to us elders as the Washoe process, or the method of treating silver ores by pan-amalgamation, which he introduced on the Comstock Lode. Of his other praiseworthy achievements, and of his operations as a miner, concerning which I have little personal knowledge, I say nothing now. But to his very great usefulness as a millman, his readiness to investigate any promising improvement, and to accept it when found good, his honesty and his generosity, I bear willing testimony—all the more readily because he always seemed to me rather modest in claiming credit to which he was justly entitled.

So far back as I can remember—indeed from the very foundation of this journal, I have reason to believe—there was no more welcome visitor to the office of the MINING AND SCIENTIFIC PRESS, to which his alertness, his cheery enthusiasms, and his quiet humor, always brought pleasant light and warmth. Many years have passed since I last met him. Now that he has gone, I wish to say that I am glad that I once knew him, and that I shall ever hold him in loving remembrance.

A. D. HODGES, JR.

Boston, January 27.

Thawing Powder.

The Editor:

Sir—It is not known to the writer whether the system of thawing powder with hot air is in use or not, and I submit this sketch of a device that has passed through the experimental stage into an efficient and satisfactory thawer. Anyone who has developed a mine from a prospect to a producer, especially in a new district, where communication with a base of supplies is both seldom and difficult, has encountered obstacles requiring efficient and speedy

action. This thawer is the product of such circumstances. I have had experience with both steam and hot-water thawers, and it is my opinion that this hot-air thawer eclipses both, by eliminating danger from ignition and explosion of combustibles, and cost of installation, and it equals, if not surpasses, them in economy of operation.

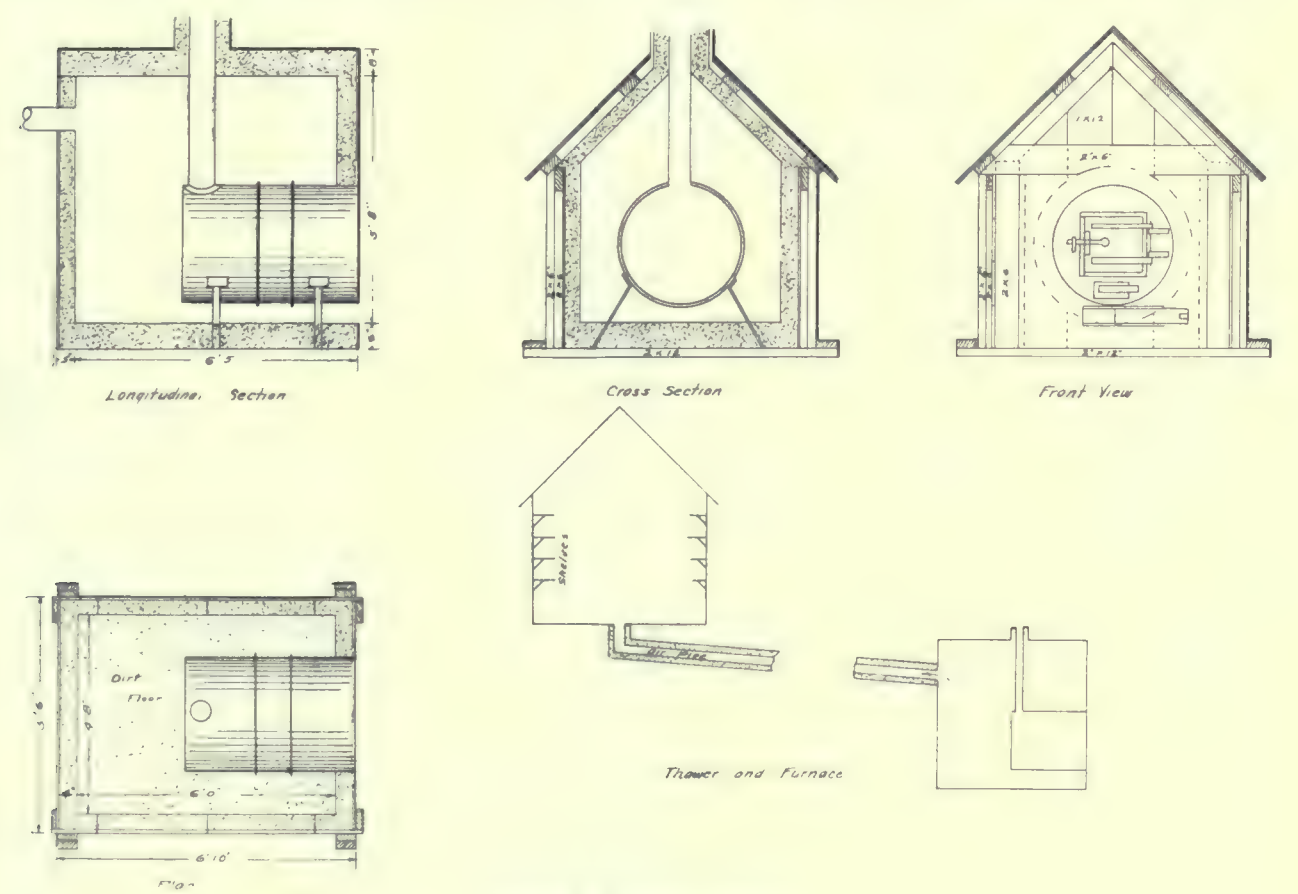

This sketch is from the original drawing. The interior lining, which holds the earth-filling in place, is corrugated iron roofing, held in position by $\frac{3}{4}$ -in. iron pipe nipples, 4 in. long, placed between the iron and board structure with bolts through the nipple. The stove is made from a gasoline tank. The fuel is green hemlock and spruce.

It requires no attention, other than an occasional firing up and regulation of the drafts. Twice the

Electricity as an Aid in Amalgamation.

The Editor:

Sir—In your issue of January 9 appears an article giving directions for the amalgamation of new copper plates, when they have not been previously silver-plated by the standard method. The writer points out some of the difficulties that attend the ‘breaking in’ of a new mill-plate. I wish briefly to indicate a simple method by which not only the difficulties mentioned may be avoided, but all the usual troubles of the amalgamator obviated. By this simple process, which only requires in the way of additional equipment an inexpensive 2½-hp. low-voltage generator, new copper plates can be prepared for use in 30 minutes; the amalgam surface is phenomenally bright and active; fouling is impossible, and the amalgam,

Apparatus for Thawing Dyanamite.

heat got so intense as to ignite the wooden supports of the roof, even through the earth-filling, being conducted by the bolts. These supports have been replaced by 8-lb. T rails and covered with corrugated iron roofing. The pipe from the furnace to the thawer is 6-in. iron, also enased to prevent loss by radiation. The floor of the thawer is approximately 6 ft. above the outlet of the furnace, and about 40 ft. distant. These distances should no doubt be greater for both efficiency and safety. A thermometer has not reached us yet, but a temperature of 100° F., I should think, could be readily obtained in the thawer—much higher, of course, than necessary. The thawer is a board building, 8 by 10 ft., and the air-pipe enters through the centre of the floor. It is giving excellent satisfaction.

W. P. ROGERS.

Goose Bay, B. C., December 18.

while soft and plastic, is tough, tenacious, and is not broken off or carried away.

To equip the usual mill-plate so that the wonderful properties of electro-chemical action can be used in connection with standard amalgamation, longitudinal or transverse strips of graphite, a few inches apart, are suspended about $\frac{3}{8}$ in. above the plate; the graphite strips (anodes) are connected to a 5 to 10 volt generator of sufficient size to furnish about one ampere per square foot of plate-surface; the plate (cathode) is also connected with the generator; sufficient water is used to make a connection between the graphite strips and the plate. This is all the special equipment required, and adds practically no additional operating cost. In preparing a new plate, the surface is cleaned with vinegar, the water and current turned on, and a weak solution of bichloride of mercury fed into the water before it reaches the

plate. In 30 minutes the plate will be covered with a beautiful coating of nascent mercury, which will hold any kind of gold passing over it, be the gold rusty, greasy, coated, silicious, arsenical, or what not; the finest particles of gold in slime are held as readily as the larger particles, and as long as the electric current is passing no more amalgamating troubles will occur. The pulp is then passed over the plate in the usual manner, but extra water can be employed without detriment.

Quicksilver can be used in the usual way, or it may be supplied in the form of a solution; the action of the electric current cleans the gold and destroys organic matter and impurities. Under electro-chemical action, the amalgamating power of mercury is made much stronger than normal; with such an equipment as above outlined, gold can be amalgamated which would otherwise pass readily over the usual plate. I have found by numerous tests that with electrolytic amalgamation the tailing-assays are greatly reduced. I might add that all the statements made in this communication are not based on guesswork or theory, but are the result of a long series of tests with a plate-surface 30 in. wide and 32 ft. long, and confirm statements made by Warnford Lock in 1892.

So far as I know, the first authoritative statement regarding the great value of electro-chemical amalgamation appears in the Proceedings of the London Institution of Mining and Metallurgy, Vol. I, page 205, where appears a paper by C. G. Warnford Lock, in which he gives the results of many trials showing how electro-chemical action greatly increased the amalgamating action, and those who wish to investigate the matter are referred to Mr. Lock's paper. Not only have Mr. Lock's statements been amply substantiated, but even more wonderful results have been achieved.

ELMER ELLSWORTH CAREY.

San Jose, California, January 16.

Mining Law in Nevada.

The Editor:

Sir—The editorial in your issue of December 26, headed 'Mining Law in Alaska', was, as your articles usually are, very much to the point. That the same evils exist in all of our mining regions, especially during boom times, no one familiar with the conditions will dispute, and all but the professional stam-peders would like to see the law so changed as effectively to prevent speculators from tying up large areas of mineral land and keeping them for long periods withdrawn from entry by prospectors. I have so often had the irritating experience of finding miles of such ground held by the most perfunctory compliance with the laws—being practically certain that not one legal discovery had ever been made on any of the claims—that I am naturally very much pleased at the strong stand you take against existing abuses, and would also like to add a few remarks on the subject.

As you say, the chief value of the existing laws is in the security of title afforded by them. This security extends to everyone who initiates a title by going through the form of posting a location notice and

marking the boundaries of his claim, the presumption being, as I believe the courts have ruled, that a discovery has been made. If no such discovery was made, the entry consequently being fraudulent, the law nevertheless protects the locator in his fraud by throwing the burden of proof on those attacking his title. This is only in accordance with the fundamental principals of all our laws, which are said to abhor a forfeiture. The trouble is that it is impossible strictly to define what a discovery consists of. Assay-values of the minerals present in the rock, or the absence of such values, are no true criterion. But if a locator were to go into possession, as you suggest, and work the ground continuously for, let us say, one or two months, that might be taken as strong presumptive evidence that he had found something worth while. If the law required such an entry to be made, instead of the mere assertion of a discovery, as part of the first step toward the acquisition of a possessory title from the Government, the speculator in mining locations would be severely handicapped, and the bona fide prospector, as well as the mining industry in general, immensely benefited.

The great defect of the annual labor clause, probably, is the requirement that a specified amount of money be expended. It is absolutely impossible to judge the real expenditure by the evidence of the work performed, and therefore those disposed to evade the law feel quite safe to do so, and perhaps hire the work done at bargain-counter prices, with a 'proof of labor' for the whole \$100 worth thrown in. I regret that I cannot agree with you in expecting an abatement of this evil coming through an increase in the law-abiding element of the mining regions—at least not until the tax-dodger of the land and all his tribe have become extinct. "Everybody else does it, why not I?" is the ancient and world-wide motto of applied sophistry. In the days before the Klondike excitement, when Miner's Law was recognized on the Yukon, the owner of a claim was required to 'represent it', that is, to remain on the ground and work it during a certain month of each year, either in person or by employing someone else for the purpose. It was extremely difficult to evade that law. If a modification of it were adopted here, or if the United States requirements were a specified number of days work for each claim, instead of the expenditure of \$100, it would probably reduce the extent of existing abuses.

ANTHONY ELLFENER.

Rosebud, Nevada, January 3.

In nine cases out of ten, when timbers are crushed, the indirect cause is decay, produced by low forms of plant life. The dwindling of the timber supply has driven consumers all over the country to study the prevention of decay, and in the near future many mines will put in small plants for the treatment of timbers, after the pattern of the plants that have been designed and installed for this purpose by the United States Forest Service. By treating permanent timbers with one of the various preservatives, they may be made to resist decay almost indefinitely, at slight cost.

MINING IN SIBERIA.

Written for the MINING AND SCIENTIFIC PRESS
By CHESTER W. PURINGTON.

In eastern Russia gold mining has been in progress for 150 years. In the Tomsk, Transbaikal, Yenesei, and Altai districts operations have been continued for over 60 years.

The product has been mostly from alluvial washing. Up to 1897 the recorded yield was 216,000 poods, since which time it has averaged 2000 poods per year. Taking the gold at a conservative value of 850 fine, the gross recorded gold product has been approximately two billions of dollars. The Lena district alone, an area comparable in size and to some extent in physical conditions to the Fairbanks region of Alaska, has produced \$250,000,000 in 56 years. This district is by no means fully explored.

The foreign engineer or operator meets many strange conditions in Siberia. In the first place, the physical conditions are unusual for a mining region. The richer mining districts are situated remote from the main trunk line of railway crossing Siberia and Manchuria. Distances varying from 10 to 500 and even 1000 miles must be traversed in rough carts over execrable roads, or, where water transportation is available, by means of indifferent steamboats, in order to reach the gold mining camps from the railway.

There are few places where the grades of streams are sufficient for generating power from falling water, and room for the tailing must be artificially provided. By far the greater portion of the vast gold-bearing area is characterized by shallow alluvial deposits, consisting of three to four feet of pay-gravel capped by 10 ft. or more of nearly barren overburden. The frozen alluvium of the Bodaibo, and neighboring streams of the Lena districts, presents a remarkable exception, being from 50 to 150 ft. deep. This district is characterized by perpetual frost in the gravel and is worked largely by driving. The solid 'frost' of the Klondike and Fairbanks is rare in Siberian gravels, which are either entirely free from perpetual frost or are only partly frozen, as in the Alaska Forty-Mile district.

The gravel of the pay-channels in Siberia generally is sub-angular rather than round, so that it does not roll easily in sluices or other washing devices. It is also mixed with clay. These features tend to reduce the capacity of washing-plants.

The most remarkable feature of the Siberian gold-fields is physiographic uniformity, thus rendering it possible for general statements like the above to be made regarding an area covering more degrees of longitude than intervene between New York and Bering strait. In an area that exceeds 5,000,000 square miles and which extends from 43 to 78° north latitude, it is to be expected that there should be extreme climatic variations. Such is the case. In the Ussuri valley, north of Vladivostok, two crops of grain per season are possible. At Habarovsk, which is under the latitude of Seattle, Indian corn flourishes. In June 1907 my wife planted a kitchen gar-

den, at our property, ten miles from the shore of the Okhotsk Sea, and in three weeks we were eating radishes and lettuce therefrom. In south Siberia camels are used for transportation. North of the 54th parallel, dogs and reindeer are used in winter.

Roads are always abominable in the summer time. Both freight and passenger transportation off the main line is slow and poor, but not expensive. Wood for fuel is plenty and cheap, rarely exceeding \$1.50 per cord except in the most remote camps. Timber is good on the hills, but fit for nothing but firewood when cut in the immense bogs and valleys that characterize the country. In parts of the Ural the supply of wood for charcoal-burning has been exhausted, and peat is used. It is the only fuel employed at present on the dredges operated by the Neviansk Company.

The labor conditions are such that a rapid increase in mineral production is not to be expected. Russian peasants are fairly successful in agricultural pursuits, but not in mining. The old style of Siberian gold-miner has been accustomed to hand-shoyeling, and generally figures his product for the season in terms of the number of men and horses he proposes to employ, as for example, 500 men and 60 horses, 1000 men and 200 horses, and so forth. The progressive exhaustion of the former rich alluvials naturally interferes with this convenient method of calculating assets, and the Siberian has turned to the gold-dredge as a last resort. As yet the dredges installed have been of faulty construction and low capacity, and the results insignificant.

Siberia has never been known as a gold-quartz mining country. Parts of the Altai promise well for prospecting, and there are several small crushing mills at work in the region between Minusinsk and Kuznetsk. The lodes are fairly wide, but the ore is spotty.

A 5-stamp mill is at work, or was, last summer, at Askold island in Vladivostok harbor. The ore comes from a four-inch vein in granite and has to be sorted as mined. It contains much copper and iron pyrite, and is rather difficult to treat. It is said to be rich in gold. The mill was built by the Union Iron Works of San Francisco, and was furnished with Wilfley tables. An experimental attempt was being made to chlorinate the concentrate. According to Government figures, the mine has been operating several years and has produced over \$100,000. The cost of mining, sorting, and milling the ore was given as \$7.50 per ton.

A 10-stamp mill with concentrators was ordered a year ago from Fraser & Chalmers for a quartz mine at the head of the Selenga river, 500 miles northeast of Blagovestchensk-on-Amur. As a comment on Siberian transportation, it may be said that although the mill left England last April, going by Suez to Nikolaievsk, it will be the end of this winter before it is landed on the property. This was the quickest transport possible from London. Quartz veins exist near Nerchinsk and have been considerably developed.

The copper resources of the Kirghiz steppes of west Siberia have recently been developed to some

extent by foreign companies. The outcrops of the deposits are said to stretch over a wide area. There are also promising deposits in the north Ural, but the product has always been small. Platinum is now being dredged from several river beds in the northern Ural, and it is likely that more deposits exist still farther north than those exploited. The extreme north Ural affords an interesting field for study, as the geological conditions are similar to those upon the Shuvalof property, whence the larger amount of the platinum comes at present.

An attempt has recently been made by a German company to open some of the old silver-lead deposits of the Altai. The veins are undoubtedly large, and are said to have been proved to over 1000 ft. in depth. So far no considerable product has been reported.

Probably one reason why all forms of quartz mining in Siberia result in small output is the paternal character of the mining regulations relating to timbering, placing of machinery, and use of explosives. The laws are evidently intended to protect employees, but if strictly enforced would practically shut-down all underground work. An entire revision of the mining law so as to render it compatible with up-to-date methods would be a benefit. The laws are too liberal in some ways and too restrictive in others.

The difficulty of language will always be a hindrance to the development of Siberia by foreigners. English is spoken little even in the towns, and with the exception of the east coast, where English-speaking Chinese can be secured, all instructions to laborers must be given through interpreters.

The shortness of season is a drawback to Siberian gold-dredging; gravel from which only 15 cents per cubic yard can be recovered does not pay, as it does, for example, in California. Gravel of higher tenor than this, however, occurs in several of the river valleys which have been prospected in east Siberia, especially the tributaries of the Amur. Accessory dredging conditions are favorable rather than otherwise. At the Neviansk property in Ural experiments are tending to a lengthening of the dredging season. Mr. Barbot de Marny is authority for the statement that one Neviansk dredge in 1905 worked 248 days between March 10 to December 22. In 1906-7 the Neviansk season lasted from April 13 to January 31. The conclusions reached from several years' operations of five dredges were that the cost of work after ice forms is 30% higher than before; that the loss of time is 7% greater; and that the loss of gold is increased through freezing of the tables.

No attempt has been made up to the present to attack frozen gravel with dredges. If the gold-dredge reaches a stage of development such that frozen gravel can be successfully handled the shallower deposits of the Olekma and Vitim districts can probably be worked by this method.

Interesting developments are anticipated, now that English capital has become interested in the deep gravel-leads of the Bodaibo and adjacent creeks. Improved steam-thawing methods and systematic drift-mining should progressively decrease the cost of mining and increase the output.

PUMP SLUICING FOR GOLD.

By H. HERMAN.

*This method is almost wholly restricted to the winning of the two metals whose wide distribution in detrital form is one of their leading characteristics, namely, gold and tin, the latter, of course, in the form of tin oxide. Pump-sluicing will not solve the problem of working at a profit the deep leads of the Berry-Moolort-Loddon system, which yield about 10 dwt. per square fathom of wash-dirt, because the wash-dirt is overlaid by 300 to 400 ft. of clay and basalt-flows, which render any system but that of the deep alluvial miner out of the question. But if 3 ft. in thickness of wash-dirt be overlaid by only 50 or 60 ft. of material readily disintegrable under a jet of water issuing from a nozzle at a pressure of 50 or 60 lb. per square inch, it may be cheaper to remove the 60 ft. by sluicing than the 3 ft. by alluvial mining, with the additional advantage that the valuable mineral which often occurs in the 'overburden' in such deposits is largely extracted also. Some detrital deposits contain gold or tin throughout the whole or the greater part of their depth, and in such cases it may pay handsomely to sluice to a depth of 100 or 150 ft., where mining the bottom only would cause disastrous failure. In every case of doubt the nature of the whole deposit and the distribution of the metal should, as far as possible, be ascertained before adopting any fundamental scheme of treatment.

Pump-sluicing and bucket-dredging each has its characteristic field of usefulness, and in many cases it is easy to decide that one or the other is the only practicable method. An engineer would not suggest pump-sluicing the beds of the fast-running streams of New Zealand, where bucket-dredge mining first found a home; neither would he place a bucket-dredge on a deposit 100 ft. thick, nor on a deposit one-fourth that thickness if a few feet of valuable 'wash' lay between a hard uneven bottom below and a tough bouldery overburden above. In such cases the proposition is either adopted or rejected after consideration of the one practicable method. Numerous cases arise, however, where either method is practicable, and upon the choosing of the right one may depend the success of the venture. If the question be simply how to turn over 20 to 30 ft. of non-tenacious material at the lowest cost, in sporting parlance, assuming a sufficient water-supply, 'only one horse is in the running', namely, the bucket-dredge. In Victoria in 1907 about 10,000,000 cu. yd. of material was treated by bucket-dredges, and about 10,000,000 cu. yd. by pump-sluicing plants; the average cost per yard in the former case was under 3d., and in the latter over 10d. The reasons for such a marked difference in costs are not far to seek. First, assuming ground of equal depth and tenacity, say 20 ft., the principal work of a bucket-dredge would be to break up the face with grabs or buckets, lift the solid material in the chain of buckets a height of 40 to 50 ft. (of which 15 ft. would be assisted by

*Abstracted from *The Australian Mining Standard*.

displacement of the water in which the pontoon floats), and elevate with a centrifugal pump to the sluice-boxes 2500 to 3000 gal. per minute of sluicing water against a head of 25 ft. A pump-sluicing plant of the same capacity would have to deliver probably 3000 to 3500 gal. or more of water to a nozzle under an equivalent head of 100 to 150 ft., then raise the same water, as well as perhaps a considerable quantity of water draining from the deposit, together with the comparatively small weight of solid material sluiced, to a height of 40 to 50 ft. These figures explain why it is that a pump-sluicing plant usually requires five or six times the engine and boiler-power of a bucket-dredging plant of the same capacity. Flooding paddocks for shifting plant and building tailing dams are further serious items of 'dead work' not having a corresponding offset in the practically continuous run of a bucket-dredge. The above comparison in Victorian costs in favor of the latter is, however, rather unfair to pump-sluicing, by reason of the fact that in addition to treating ground of greater average depth (approximately 20 ft. against 15 ft.), the pump-sluicing plant had to take all the tough irregular ground that the bucket-dredge could not attack. Conditions, however, being equal, the relative yardage-costs would probably still be $2\frac{1}{2}$ or 3 to 1.

With such a striking disparity in costs, it is apparent that some weighty reasons should be forthcoming before rejecting a bucket-dredge in favor of a pump-sluicing plant; unfortunately, such reasons are frequently not wanting. The bucket-dredge, for successful working, requires fairly easy breaking ground and moderate depth. If the values be on or close to the bottom, such bottom must either be very even or soft enough to dredge evenly. Sufficient water-supply must be available to maintain floating water, the drainage-loss through loose tailing often being large. A bucket-dredge placed on unsuitable ground may suffer frequent stoppages and breakages, heavy maintenance charges, small turn-over, and a recovery of less than one-half of the gold or tin; then pump-sluicing, which is adaptable to changing ground, and permits of full inspection and clean-up of the bottom, may furnish better commercial results, despite higher costs.

This article, having for its object merely the setting forth for the benefit of laymen the chief considerations in the selection of a plant for the treatment of detrital deposits, technicalities have been avoided. It may be well to point out, however, that even after a selection of a general method has been made, the greatest care is necessary to work out details along right lines. What shall be its capacity or yardage? Where obtain a water-supply? Where draw the right line between large capacity, high capital expenditure, and low working costs on the one side, and smaller capacity, lower capital expenditure, and higher working costs on the other? What sort of a pump-sluicing plant shall be provided? A number of tin-sluicing plants in New South Wales consist of two portable engines, side by side on the ground, working nozzle and gravel-pumps respec-

tively, and when the limit of operations from one position has been reached, land transportation is necessary to the next location. Such plants are owned by the Tingha Tin Dredging, Union Tin Dredging, Ferris, and Stannum companies. One plant of the Elsmore Co. pumps water 240 ft. high to a reservoir, and thence takes nozzle pressure by gravitation, sufficient fall being available for this purpose, as also to get rid of tailing by ground sluicing. The Bourke's hill mine has for some time worked two ground or stationary plants; recently, with altering conditions, it has been deemed advisable to place one plant on a larger pontoon. The Briseis Extended Co., in Tasmania, lifts its wash through a 16-in. pump over 120 ft. in one lift; the Pioneer Co., in the same State, prefers to divide about the same elevation into two lifts, using three plants on pontoons in its operations. The latter company also, having a good water-supply under pressure, needs to employ steam for gravel-pumps only, and is now well under way with a hydro-electric installation which will obviate the use of steam altogether. The South Mount Cameron mine, Tasmania, resembles the Elsmore, except that the permanent pumping plant sends water under pressure direct to the nozzle, instead of using an intermediary dam. The bulk of pump-sluicing plants, however, consist of both nozzle and gravel pumps, worked by steam, and erected on a pontoon for water transportation to a new site after the excavation of each paddock. While the range from the 10-in. gravel pump and 150 to 200 effective horse-power of the 'Standard' plant of the Castlemaine district to the 16-in. pumps, with four times the power, of plants like the Y-Water at Emmaville, New South Wales, and the No. 2 Creek at Avoca, Victoria, give the engineer small scope for consideration before making final recommendations involving matters of capacity, first cost, and working expenses. Probably the most powerful pump-sluicing plant yet constructed is on its way to Billiton, in the Dutch East Indies, from the yards of a Melbourne engineering firm. This plant will carry over 1000 hp. on a steel pontoon 70 by 35 by 6 ft., drawing 5 ft. of water, and independent vertical compound condensing engines of 375 and 760 hp., respectively, and will drive a 16-in. nozzle-pump and a 16-in. gravel-pump, the latter lifting its burden to a maximum height of 120 feet.

Peru produced 207,810,365 kilograms of silver in 1907. The principal producing departments were Junín, yielding 108,026,229 kg.; Lima, 32,941,773 kg.; Ancachs, 25,620,948 kg.; Cajamarca, 13,731,639 kg.; and Huánuco, 10,446,446 kg. The larger amount of this production, reaching 42,517,948 kg., was in the form of argentiferous matte.

Sulphur is found in buried marine sands on the coast of the Department of Piura, Peru, near the town of Sechura. During 1907 La Compañía Azufrera Sechura produced 80 tons refined sulphur in the form of 'flowers of sulphur', grain, and rosin, and 4500 tons of crude ore containing by assay 1800 tons of sulphur, or 40 per cent.

JALISCO AND COLIMA.

Written for the MINING AND SCIENTIFIC PRESS
By W. A. SCOTT.

Extensive grain-raising areas exist in Jalisco, and the general aspect of the region is prosperous as regards agriculture, as well as mining. The country is fairly well watered by the Rio Santiago and its tributary streams and head-water lakes; and by the Ameca, Tuxpán, and Armeria. The Santiago, which drains the country from Lake Chapala northwesterly, including Etzatlán and Hostotipaquillo, flows through the territory of Tepic, and empties into the Pacific near San Blas. It is considered the greatest river in Mexico, as regards the volume of water it carries, though other streams have greater length. The route of the Southern Pacific branch railway,

miles to Tequesquite will give the mine-operators of the Hostotipaquillo district better transportation facilities in the near future. Between Tepic and Tequesquite is where the greatest engineering and most expensive work will be required, as part of the route between those places is over mountains and across deep canyons. That part of the road from Culiacán to Mazatlán is nearly finished, and it is reported that train service will be commenced on that division before March 1.

Guadalajara is one of the best built cities of Mexico, and its prospective connection with the Southern Pacific coast-line railroad, and the recent connection with Manzanillo by the completion last month of the Mexican Central's Tuxpán-Colima division, give to the city an auspicious future as a commercial and railway centre. Viewing the cultivated valleys and

Manzanillo.

as laid out between Mazatlán and Guadalajara, crosses the Santiago 15 miles east of San Blas, and thence takes a southeasterly course through Tepic, Ixtlán, Tequesquite, Tequila, and Orendain, the last being the junction point of the new road with the Mexican Central branch from Guadalajara to Ameca. This route, while it may be said to pass up the Santiago river, keeps from 12 to 25 miles away from the stream. The mines of the Hostotipaquillo district, including the Casados, El Favor, Mololoa, Virginia, and Mexico, Mina Grande, and Cinco Minas, are situated between the railroad and the river, extending as a chain from northwest to southeast. Tequesquite station, on the new road, is within 10 to 20 miles of the mines of the district, whereas Etzatlán, the present nearest forwarding station on the Mexican Central, is 40 to 50 miles distant. The railroad is practically finished from Orendain to Tequila, a distance of about 35 miles, and the further extension of 20

plains of Jalisco, the observer notes the absence of the maguey plant; instead are fields of corn and other cereals, along with orchards, and groves of eucalyptus trees, all suggesting better industrial conditions. The length of the railroad from Guadalajara to Manzanillo is 230 miles. That part from Guadalajara to Tuxpán extends through the productive Sayula valley, thence over a divide to that of the Tuxpán. Here the traveler obtains the first sight of the active volcano of Colima, which continues in plain view till the train passes far to the south of the town of the same name. The route from Tuxpán to Colima is down the Tuxpán river, which flows in a deep canyon a large part of the way. In following this course the train passes through 13 tunnels, all arched with concrete blocks; it also crosses 15 steel bridges, one of which spans the main stream, the others spanning in-coming branches. Before reaching Colima the road leaves the Tuxpán valley, and

crosses a divide into the country drained by the Colima and Armeria rivers. From this side is obtained the most advantageous view of the volcano, a gray cone-shaped peak, rising to an altitude of 14,360 ft. above the sea. Early in the morning on passing here the writer saw the smoke and gas emitted from the crater ascending almost vertically 50 to 100 ft., and gradually drifting away as a cloud in the sky. In appearance this column of smoke and fume resembled that rising from the stack of a smelter, except that the volume from the crater seemed many times greater than that being emitted from any chimney. At mid-day the atmosphere must have become more moist, as the smoke no longer ascended, but settled about the crater and hid from view the apex of the mountain. In the vicinity of Mount Colima is a similar peak, having an extinct crater. Colima, the capital of the State of that name, is an attractive place, with well-kept streets and plazas, adorned by the tropical verdure pertaining to this district. From here the train runs to Manzanillo in 5 hours,

Part of Jalisco, Mexico.

passing through the plain and the valley of the Armeria river, with banana fields, cocoa-nut groves, and spreading palms. Along the route are seen the steep thatched roofs of the huts and houses of the inhabitants, reminding one that during the long rainy season the roof is the most essential part of the dwelling. Manzanillo is a good natural port at the head of a small bay which extends inland three miles from the open sea. Protecting the landing is a 200-ft. breakwater, recently finished by the Mexican Government. The surrounding hills are uneven, rolling, and covered with bushes and scrubby timber. The railroad leads through a cut made in the low hills, the track then extending 20 miles down the coast upon a peninsula separated from the mainland by a lagoon of equal length. Here the lagoon is crossed to the mainland. The coast steamships that call at the port of Manzanillo belong to the Pacific Mail line, the Kosmos, Canadian-Mexican, and Mexico National. A large German vessel which recently landed

at this port with a cargo of railroad ties from Japan for the Southern Pacific Co. will now ply regularly between Seattle and Central American ports, and compete for the freight and passenger traffic of the coast towns.

C. R. H., Hermosillo, Mexico: Wollastonite.

J. J. M., Oat Hill, California: An earth rich in limonite.

C. W. L., Salt Lake City: Mottled quartzite with pyrite and pyrrhotite.

R. C. K., Yerington, Nevada: Crystalline limestone stained with malachite.

M. J. O'C., Denio, Oregon: Material is opal, some of it of the variety known as precious opal.

F. J. J. Millett, Nevada: A garnet-epidote-calcite rock, the product of contact metamorphism, originally a lime bearing sediment.

E. D., Salt Lake City: No. 1, quartz-calcite-epidote rock, a metamorphosed sediment; No. 2, aplite; No. 3, rock intermediate in texture between granite porphyry and rhyolite; No. 4, gabbro.

L. H. G., Los Angeles: No. 1, granite-porphyry or rhyolite-porphyry, possibly syenite-porphyry; No. 2, metamorphic rhyolite; No. 3, weathered rhyolite; No. 4, rock is shale, white coating is very thin and seems to be kaolin but it cannot be isolated for precise determination from the rock in which kaolin is present in large amount.

J. J. M., Reno, Nevada: No. 1, garnet-chlorite (vesuvianite?) rock, a product of contact metamorphism containing small quantities of pyrite and molybdenite; No. 2, crystalline limestone; No. 3, badly weathered quartz-feldspar-mica rock with much limonite and some calcite. The surviving texture is nondescript, so that it cannot be determined whether the rock is granite or arkose without microscopic study; No. 4, peridotite, much serpentinized; No. 5, quartz-chlorite schist; No. 6, granitite.

W. D. McP., Santa Cruz Mtn., California: No. 23, powder from drilling; no definite determination could be made; the powder seems like that of a basic volcanic rock somewhat metamorphosed; No. 24, well developed pyrite crystals and massive pyrite in a much sheared and brecciated rock in which calcite and quartz veins are seen, with some serpentine and chlorite; no definite name can be given to such an aggregate; No. 25, small amount of pyrite and calcite in a rock crushed and sheared beyond definite recognition; some serpentine is present; it appears like a metamorphosed basic volcanic; No. 26, silicified basic volcanic breccia; No. 27, serpentinized and silicified basic volcanic rock.

THE GRANBY SMELTER.

By ROBERT KEEFER.

*At Grand Forks, British Columbia, in the narrow valley of the North Fork of the Kettle river, a short distance north of the main town, is situated the smelting plant of the Granby Consolidated Mining, Smelting & Power Co., Ltd., the largest copper smelter in Canada. The position is such that the prevailing winds carry the sulphur fume through a ravine to the east, or else up the valley of the North Fork: thus the air at Grand Forks is exceptionally good for a smelter town. South and east of the town are extensive orchards, where choice apples and other fruits are grown, quite unaffected by the proximity of the big plant. The smelter-site is well above the river, giving a large slag-dump with a minimum amount of haulage. A dam across a narrow part of the valley, a short distance above the plant, forms an artificial lake of generous proportions, storing water for all purposes during the season of low water, which is in the winter. Sufficient fall is obtained to operate an electric generating plant.

The first furnace was blown in on August 21, 1900, at which time the plant consisted of two furnaces, having a joint capacity of between 600 and 650 tons daily. This was the first plant to smelt ores from the 'Boundary.' It had been built on the theory that the raw ore would give a low-grade matte on the first smelting, and would require re-smelting to bring the matte up to shipping grade of about 60%. But it was soon demonstrated that the ore would yield a sufficiently rich matte with the first smelting, and both furnaces were thereafter used for treating ore direct, thus immediately doubling the supposed capacity of the plant. For several years the final product was matte, which was sent east for further treatment. A converter was then installed, effecting a large saving in freight and in converter charges. The smelter capacity has been continually increased, until today it averages between 3000 and 3200 tons daily, with eight 44 by 210-in. furnaces in blast. The best week's run yet made was 24,000 tons in seven days, being an average of 3425 tons every 24 hours. Since the plant has been in operation, a total of 4,761,657 tons has been reduced up to December 1, 1908. The greater part of this tonnage has been taken from the Granby company's mines in Phoenix, the rest being custom ore from various adjacent camps.

The principal mining properties of the Granby Consolidated Co. are situated at Phoenix, about 15 miles distant in an air-line, and 25 by railway from the smelter. The elevation of the mines is 5200 ft., 3000 ft. above the smelter. Two railway systems, the Canadian Pacific and the Great Northern, have lines connecting Grand Forks and Phoenix. About eighty 50-ton and eighty 40-ton ore-cars, and six 150-ton locomotives, are employed by these roads in hauling Granby ore from the mines to the treatment plant. The Phoenix mines comprise a group of

claims, among which the most important are the Old Ironsides, Knob Hill, Victoria, Monarch, and Gold Drop, the total area exceeding one thousand acres. The ore, which occurs in deposits of great size, is mined in immense stopes, in which practically no timber is used, the ore standing quite firmly. This system reduces mining costs to an extremely low figure, and is one of the circumstances making possible the handling of the extremely low-grade ores commonly found in this district. The Boundary ores are practically self-fluxing, the occasional addition of a small quantity of heavy sulphide being all that is necessary for a perfect smelting mixture. The proportion of coke used is 12½%. The coke comes from the mines of the Crow's Nest Pass Coal Co., at Fernie, B. C. The ore on reaching the smelter is dumped from hopper-bottom steel ore-cars into the main receiving bins, which are reached by the tracks of both railways. The bin structure is divided into five rows, with a total width of 75 and a length of 764 ft. Over the entire length of each row of bins extends a railway track, so that every bin may be filled direct from the railway cars. Three-rows of bins are used for ore and two for coke. The ore-bins are divided into compartments 13 ft. long, having hopper bottoms sloping toward the chutes at an angle of 45°, so that they can be completely emptied without shoveling. There are 150 of these compartments, with a total capacity of 15,000 tons. The coke bins are not divided into compartments, and are flat bottomed. Railway scales are provided for all tracks, on which the ore is weighed before going to the bins. Under the bins, 6 ft. below the chutes, run three 20-in. gauge tracks, on which the feed trains operate, each inner track serving two rows of bins, and the outer track serving one row. The feed trains consist of three large cars, of a total capacity of four tons of ore, plus the requisite amount of coke. These cars are drawn by a 30-hp. electric locomotive, and are filled from chutes operated by a lever, from an elevated platform provided for the purpose. Coke and ore are mixed in the proper proportion directly in the charging car, the coke being placed in the bottom, and the cars weighed, after which the ore is added. This done, the charge is weighed a second time and run to the furnaces. Each train of cars feeds two blast-furnaces, and handles 750 to 900 tons of ore in 24 hr. One car in every ten of the Granby ore, and all of the custom ore, is run through the sample mill, the remainder going direct to the furnaces. The Granby ore is crushed to between 4 and 6 in. at the mines.

The feed cars have a raised bottom like an inverted V, and dump from both sides. Two sets of wheels are provided, one of narrow gauge for the loading tracks, and one of a gauge of 65 in. After receiving the charge, the feed trains go into the furnace room, the cars always being in front of the motor. The cars are run directly inside the upper part of the furnace, being supported upon entering the furnace by the wide-gauge wheels, which here run on tracks on the sides of the furnace. The three feed cars are of sufficient length to fill the furnace from end to

*A student contribution to the Mining Engineering Society at the State College of Washington.

Converter Room, Granby Smelter.

Pouring Blister Copper, Granby Smelter.

end, and upon reaching the proper position are dumped by means of a lever operated from either end of the furnace. The ore and coke is well distributed over the furnace by this method.

Two stacks are provided to dispose of the fume from the battery of 8 furnaces, one stack being at each end of the plant. These are connected with the down-take pipes by brick dust-chambers of large dimensions. The flue-dust, which carries about $1\frac{1}{2}\%$ copper, is briquetted and smelted. On the furnace floor, the slag and matte run into a settler placed at the front end of each furnace. From this, the slag runs into a second settler, with a slag-spout on each side. Two slag tracks are provided for each furnace. The track on the left of the settler is on a considerable grade and runs further back than the right-hand track. This arrangement provides for two slag-pots on one side of the settler, and one on the other side. When one of the left-hand pots is filled, the brakes are released and the second pot is run under the spout by gravity. As soon as both pots on the long track are filled they are hauled away to the dump, the slag stream meanwhile being diverted to the right-hand pot. The slag is removed from the furnaces by 14-ton steam locomotives, of which there are four; one for each two furnaces. One locomotive, and between 10 and 12 slag-cars are constantly kept in reserve for use in emergency. An ingenious arrangement is used to dump these slag-cars. The slag-bowl rests on a toothed wheel at each end, and is so mounted that when filled the centre of gravity is above the centre of equilibrium. A catch being released, the pot is automatically tipped. When empty, the centre of gravity is altered, so that the pot returns by itself to its original position. The matte is tapped into a 3-ton cast-steel pot, placed on the right of the settler. A crane traveling the length of the furnace room carries these pots, when filled, to the converter room, and replaces the empty pots. When the pot containing the molten matte reaches the converter room, it is taken in charge by a 40-ton Niles crane running the length of the room, and is dumped into the converter to be blown to blister copper. There are at present three converter stands, but this equipment is becoming inadequate, and the converter room is being doubled in size, three additional stands being installed. The converters are lined with a mixture of clay and highly silicious ore, the lining being done by the usual automatic tamping device operated by compressed air. Each lining is used several times. When conversion is complete, the copper (blister) is poured into moulds running on a track directly beneath the converter, and cast into bars. The blister copper, carrying from 98 to 99% copper, is shipped to New Jersey for electrolytic refining.

The converter slag is poured off 3 or 4 times during the conversion of a charge. This slag is poured into a large pot, which is placed on an automatic pouring device. This gradually empties the slag into the buckets of a slowly ascending elevator that pass under a stream of water, cooling the molten slag, and hardening it sufficiently to allow of dumping it

into a bin. The converter slag contains a large amount of copper, and goes back to the furnaces. Electric power is used throughout the entire plant, most of which comes from the West Kootenay Power & Light Co.'s plant at Bonnington Falls, near Nelson, B. C. Originally the entire smelter was run by power from the company's electric plant, situated on the North Fork of Kettle river, below the artificial 'Smelter Lake.' This has long since been outgrown, and is now mainly used for lighting the town.

A large new blower-room is rapidly being completed. This is being built of brick and steel, to replace the old wooden structure, and will contain 8 Root blowers, and two converter blowing-engines, all driven by electric motors. This building will also contain several motor-generators to furnish direct current for operating the cranes and electric locomotives.

The Granby Consolidated Co. is capitalized at \$15,000,000, of which \$13,500,000 has been issued. Dividends aggregating \$3,508,630 have been paid, the latest being in December 1908, when a dividend of \$270,000 was paid, at the rate of 2% on the outstanding stock. The dividends are paid quarterly, the rate thus being 8% per annum. The dividend rate prior to 1908 was 12%, the reduction being due to the low price of copper.

Lead in ores may be determined by the following method proposed by Low (*J. Am. Chem. Soc.*, XXX. 587). The Pb is obtained in the form of sulphate by the ordinary method (treating with HNO_3 and finally evaporating with H_2SO_4). The PbSO_4 is dissolved from the insoluble matte by means of a hot solution of $\text{NaC}_2\text{H}_3\text{O}_2$ containing a little free acetic acid. From this solution it is precipitated by $\text{K}_2\text{Cr}_2\text{O}_7$ (on 0.5 gm. of ore use 10 c.c. of a 5% solution). Boil for a few minutes, filter, wash once only, then open up the filter, and rinse the PbCrO_4 with a hot solution of $\text{H}_2\text{C}_2\text{O}_4$ into the flask, add alcohol, and boil until all the CrO_3 has been reduced, and the precipitate converted to PbCrO_4 . Filter, and wash 10 times with cold water, treat paper and all in a flask with hot dilute H_2SO_4 , and titrate with standard permanganate. The acetate solution for dissolving consists of a cold saturated solution diluted with an equal bulk of water and 40 c.c. of 80% acetic acid added per litre. The oxalic solution is made up of cold saturated solution 1 part, water 3 parts. The permanganate solution as used for Fe titrations is too strong; 1.5185 gm. $\text{K}_2\text{Mn}_2\text{O}_8$ per litre affords a solution such that 1 c.c. equals 1% lead.

Ancachs is one of the largest silver producing departments in Peru. It is also notable for its large deposits of coal, including bituminous, anthracite, and lignite. Within the last four years the mining of coal has increased rapidly with the development of silver-smelting, which industry is increasing despite the present inaccessibility of the district. A railroad is projected from the coast. When built it will bring about a great development of mining enterprise.

MAKUSHIN SULPHUR DEPOSITS, UNALASKA.

Written for the MINING AND SCIENTIFIC PRESS
By N. OLIVER LAWTON.

From time to time it has been rumored that inexhaustible deposits of sulphur existed on the island of Unalaska, in and about the summit of Mt. Makushin; and thus it happened that in the summer of 1906 I made a trip to Unalaska, prepared to ascend Mt. Makushin and solve the problem of the possible commercial value of the sulphur contained in the ancient crater and about the summit. The island of Unalaska is about 1730 miles north of west from Seattle, Washington. It is in latitude $53^{\circ} 30'$ north, longitude $166^{\circ} 30'$ west of Greenwich, and pertains to the territory of Alaska. It is the second largest of the Fox Island group of the Aleutian archipelago and fourth in line off the Alaskan peninsula. There are good harbors on the eastern, northern, and western coasts, where steamers can find safe anchorage and protection from storms, but fogs prevail along the coast and it is often difficult to get in and out. On the northeast coast of the island is Unalaska bay.

Northern Portion of Unalaska.

in which are situated the ports of Dutch Harbor and Unalaska. These ports are perfectly protected from storms; they are only a little off the course of steamers plying along the Pacific coast between Seattle and northern Alaska, and for a great many years were regular ports of call.

The Dutch Harbor port is situated on an island in the bay, and is the supply station of the North American Commercial Co., a company engaged in sealing and trading. There are about 20 buildings, including general store, manager's house, boarding-houses, warehouses, and the like, all owned by the company. A marine hospital (now closed), owned by the United States Government, is situated here, and it is the residence of a customs officer.

The Unalaska port is the headquarters or supply station of the Alaskan Commercial Co., a company extensively engaged in fishing and trading. It is the largest settlement on Unalaska island, having over one hundred dwellings, a Greek church, Methodist mission, U. S. school (now closed), wharves, warehouses, and general store. It is also the residence of a U. S. Deputy Marshall and of the Mining Recorder. The U. S. revenue cutters make the harbors their base of operation in watching the seal fisheries and customs. It is a very easy matter to reach Unalaska island during the months of June, July, August, and

September, by taking passage on the Alaska steamers which leave Seattle for Nome.

The climate is moderated by the Japan current, which passes along the southern shore, so that it is never extremely cold near the coast. Strong winds prevail all the year round. The climate appears to be healthy, although the weather is excessively rainy and foggy, especially during the nine months from September to June; during this time there are constant fogs, rains, or snow; the snow gradually replaces the rain inland toward the mountains, where considerable areas are covered with perpetual snow. The U. S. Geological Survey gives the average rainy days per year as two hundred and fifty-nine. The best weather occurs during June, July, and August; still, fogs and rains are frequent even then. At this time of the year the snow disappears from the coast, the valleys, and the lowlands; and usually by the

Smoke Issuing From Crater.

middle of August a great many peaks and ridges near the top of the mountains are bare, as well as considerable portions of the lower slopes. This is the best time to visit the mountain regions, as the areas of rock exposures are greatest, the weather mild and free from snow-storms, and the wind not so continuously strong.

Makushin mountain, on which the sulphur deposits are situated, is still an active volcano, in the solfataric, but not eruptive phase. It stands near the western part of the north end of the island. The maps give the elevation as 5691 ft., while the aneroids I carried gave 5365 ft., the elevation being checked on different occasions. There are several ways by which the summit can be reached from Unalaska or Dutch Harbor. The safest and surest route appears to be by way of Broad bay; it requires more walking, but it is the best trail and there are good places to camp at convenient distances. It is well known to the Indians, therefore they can proceed in fairly foggy weather—an important consideration, as fogs occur frequently and unexpectedly. This route is 6 miles by boat from Unalaska to Broad bay, and 13 miles by trail from Broad bay to the summit.

It is evident from a study of the volcano that Makushin was once violently eruptive, sending forth volcanic material such as ashes, lapilli, scoriae, and

bombs. As the eruptions subsided, peaks and ridges of volcanic rock were left around the summit, making what may be called the outer rim of the old crater and forming a basin several hundred feet deep, now filled with perpetual snow. This rim is shaped like a horse-shoe, making the basin $1\frac{1}{2}$ miles wide (N.E. to S.W.) by $2\frac{1}{4}$ miles long (S.E. to N.W.), open, and grading toward the northwest. During the eruptive phase, the volcano was probably more or less explosive, and the opening in the outer rim toward the northwest is undoubtedly due to a terrific explosion at this period. The basin or old crater must undoubtedly have a very irregular surface underneath the snow. It is now filled with snow to the top, where the strong winds keep it smooth and concave, or saucer-like. The depth of this snow can only be conjectured, but I think it is safe to say it will average over 100 ft., and in places it might reach 200 ft. or more in thickness. This snow is practically ice below the surface, the action of the sun, rains, and pressure causing the consolidation. The heat from the gases, and the warm earth, with an occasional vent in feeble operation, have melted the snow around the edges of ridges within the crater, forming caves underneath it, and I was thus able, in places, to go under the snow-cap as far as 75 ft. Some incrustations of sulphur were found, but most of the ground thus exposed was soft volcanic ash.

The sulphur deposits are within the old outer rim, or crater, on the summit of Makushin mountain. Almost in the centre of this crater, ridges of volcanic ash, with scoriae and bombs, protrude through the snow. These ridges are covered with innumerable holes, cracks, and vents, from which are issuing steam and hot vapors, indicating the present activity of the volcano. Hardly a space 2 ft. square can be found on the ridges which does not contain several of these small holes or vents; there are also several large vents, 10 ft. or more in diameter, through which the gases rush with a loud roar. The vapors or gases are composed principally of sulphuretted hydrogen and sulphurous acid, the sulphuretted hydrogen largely predominating. The deposits are incrustations of crystallized sulphur, formed by the cooling of the mixed gases in contact with the damp volcanic ashes and snow at the surface, and by sublimation. The incrustations of sulphur are not very thick, varying from a few inches to 10, up to 14 in. thick, and occasionally a small spot may be found which measures 18 or even 24 in., but in such cases the deposit contained considerable volcanic ash. From the method of forming these deposits it appears impossible for them to possess any great thickness. The gases leave the interior of the earth at a high temperature; the passage-way becomes heated, and the gases cannot cool before they reach the surface; as soon as the deposit attains a certain thickness, it begins to act as a non-conductor and becomes heated until the gases are no longer cooled sufficiently to cause precipitation. I found that 10 to 14 in. was the average limit of thickness of the deposit, and often 4 to 6 in. of the bottom would be mixed with volcanic ash. This was equally true of the deposits found in a quiescent state under the snow-ice, as well

as those on the active ridges still in process of formation; in other words, the thickness and general formation of the sulphur deposits were about the same where cool and where no activity was apparent, as where the vapors and steam were still escaping. Such cooled deposits were exposed in the caves under the snow, along the edge of the active ridge, as further proved by a tunnel which I drove 21 ft. under the snow from one of the caves. I also sunk test pits at other points.

After the surface crust of sulphur was passed, I encountered volcanic ash of varying color and hardness; the color varied from nearly white to dark gray or brown, and the hardness from a soft ash that could be excavated with a shovel to a more hardened material that had to be loosened with a pick. None was found that could not be excavated with a pick and shovel, except an occasional bomb. The temperature of this ash under the sulphur deposit was warm or hot, depending upon the activity of the vents. We often made tea by digging a hole in the sulphur, setting the pot therein, and letting the hot gases heat the water. At one of the large vents we put in a pick-handle, and it was scorched brown but did not catch fire. In all of the test pits, the temperature increased rapidly with depth. Some were sunk a little way from the active part of the ridge, but were so hot at a depth of 5 ft. that they had to be discontinued. Even the bottom of the tunnel which was driven from one of the ice caves was quite warm in the end, and this was 75 ft. from any place where volcanic action was visible.

There is exposed, free from the covering of the snow, 12 to 15 acres of surface, most of which is giving forth gases through small vents. About three acres of this, covering the top of the ridges, and as far as I could see under the snow, contains the deposits of the cleanest, thickest, and best sulphur. They are from 4 to 14 in. thick, and might average 9 to 12 in. The remainder of the exposed surface is covered irregularly with deposits of sulphur, but of inferior grade, being mixed with the volcanic ash in all proportions. The vapors were quite thick in places, and it was difficult to breathe. When the wind was strong we would have to approach the crater 'down the wind', and there were times when the wind would blow the vapors so that it was impossible to continue our exploring. I had to wait until the wind was just right, or when there was no wind at all, for examining the ice-caves under the snow. The best condition was with no wind, but such times were rare. I managed, however, by watching and taking advantage of every favorable chance, to get everywhere on the exposed crater and into a great many of the ice-caves under the snow. There is always the possibility of the volcano becoming eruptive or explosive; in fact, it is reported that such activity occurred last year, covering the settlements of Dutch Harbor with several inches of volcanic ash. The rumors which have clustered about this ancient volcano on the island of Unalaska, claiming the existence of inexhaustible sulphur deposits, are born of the imagination, without sufficient basis of facts to justify most of the assumptions that have been made.

MINE SURVEYING HINTS.

Written for the MINING AND SCIENTIFIC PRESS
By EDMUND D. NORTH.

In taking transit sights underground, the writer has found it advantageous and convenient to have inclined cross-hairs in the telescope, in addition to the regular vertical and horizontal hairs ordinarily used. These hairs should be inclined at about 30° from the vertical, and should cross exactly at the intersection of the vertical and main horizontal hairs. In taking observations on a plumb-wire or wires, as used in transferring surface lines underground, the usefulness of these inclined hairs can readily be seen by reference to the accompanying figure. Close behind each plumb-wire is nailed a light strip of wood, 1 by 3 in., and on this is fastened, by two thumb-tacks, a small sheet of white paper on

which is a straight black line, A B. The paper is so placed that the line A B will be horizontal; a candle is hung in front of the paper and to one side of the plumb-wire. As the plumb-wire will always swing, the telescope is pointed at it approximately, and clamped in both vertical and horizontal motion. By observing the wire as it moves, the transit can readily be so set that the plumb-wire will vibrate equally on either side of the vertical cross-hair, intersecting the inclined cross-hair and the line A B in points C and D. There will always be some irregular vibrations which need not be observed, but the centre of the average vibrations can be easily ascertained by this method. This does away with the use of a graduated scale with tangent-screw, placed behind the plumb-wires, as used by some engineers for ascertaining the centre of vibration, and also has the advantage that the plumb-wires can be left entirely alone after this simple apparatus is placed behind them, as no assistant with light or scale is needed.

Another advantage in these inclined hairs is that they enable the observer to more closely bisect a plumb-bob cord, particularly in a short sight where the cord covers a much greater field than the vertical cross-hair. Still one more advantage in their use is the fact that they so prominently identify the main horizontal cross-hair, that it is practically impossible, in taking vertical angles, to mistake a stadia hair for the main horizontal hair, a mistake otherwise easily made on a candle-lighted object.

Mistakes in tape reading and recording may be avoided by the following method. In drifts and cross-cuts, the distance between stations is measured horizontally from the transit to a point on a plumb-bob string at the station ahead. This point is marked at instrument-height by means of a small knot that can be raised or lowered. The transitman holds the tape, stretches it twice on the line to be measured, and then records the distance without mentioning it. At the next set-up the assistant reads the horizontal tape to the back-sight. If his reading checks with the previous one it shows two things, namely, that the distance was properly measured, and that it was properly recorded, and it is then marked with a small check-mark. This extra back measurement takes only a moment, and will be found well worth while, as mistakes are not infrequently made in this part of the work.

For low-grade copper ores containing much iron, the following method of estimation is recommended by T. R. Marshall: 1 to 3 gm. of finely powdered ore is treated in a flask with 20 c.c. nitric acid and 10 c.c. sulphuric acid, on a hot plate or sand bath. The process is continued until dense fumes of sulphuric acid have been emitted for ten minutes. The addition of hydrochloric acid should be avoided, as it is difficult to eliminate the last traces of chlorine and oxide of nitrogen, owing to secondary reactions occurring with the sulphuric acid. When the contents of the flask have cooled, dilute sulphuric acid and a number of pieces of sheet zinc are added. The best material to employ is the ordinary commercial sheet-zinc. This is cut up into a number of equal-sized squares. In any particular batch of assays an equal number of squares should be used for each assay, and a blank test run to estimate the effect of the zinc on the cyanide solution, as traces of copper might be present. To continue, with the aid of gentle heat, the zinc is quickly dissolved and immediately the reaction is completed the contents of the flask are thrown on a rapid filter of loose texture. The filter paper retains the reduced copper and the insoluble. The filter paper is then pierced, and the residue washed by hot dilute nitric acid into a beaker. The copper in solution as nitrate is then estimated in the usual way by standard cyanide solution after the addition of ammonia. If the same quantities of nitric acid and ammonia are used, and the temperature and volume of the solution are maintained the same in each assay, and a daily control run with a solution containing a known quantity of copper, the results will compare favorably with the electrolytic method.

COMPANY REPORTS.

GOLDFIELD CONSOLIDATED.

George S. Nixon, the president of the Goldfield Consolidated Mines Co., in reporting the progress made for the year ending October 31, 1908, states that the cash on hand, including ore in transit, amounted to \$911,295, the new mill and its equipment having been paid for, with the expenditure of \$900,000. The plans of the company have been carried out by the construction of a 100-stamp mill and cyanide annex having a capacity of 600 tons per day, also a railroad from the mines to the new mill, together with pipe-line and compressor plant. During the year no labor troubles have hindered operations. Litigation over apex rights has been ended by settlements with neighbors. While working costs have averaged \$11.27 per ton on ore treated in the Combination mill, the expense (which includes mining, milling, and transportation) was reduced to \$8.81 in October. With the new mill the cost is expected to be \$6 per ton, of which \$3 will be for milling. Using the Combination mill and the new plant, it is expected to treat "not less than 650 tons per day, of a value equal to that supplied during the year to the Combination mill," namely, \$40.21 per ton. This "ought to net the company" not less than \$550,000 per month.

During the year the mines of the company have yielded 32,755 tons of ore, averaging \$41.50 per ton, and 12,254 tons of \$7.76 stuff, now on the dump. The Combination 20-stamp mill treated 28,473 tons, yielding \$1,145,157; at the same time the lessees mined 25,540 tons, containing \$945,196; thus the output was 70,549 tons, having a gross value of \$2,400,191.

The report of the general manager, J. H. Mackenzie, gives additional information: The company now controls 380 acres, besides minor interests. The new mill started on December 26, 1908, on a process of treatment based upon experience in the Combination mill. Briefly stated, the process consists of crushing first in gyratory rock-breakers and then by stamps, with re-grinding to slime in tube-mills; amalgamation both before and after tube-milling; concentration on Deister slime-tables; cyanidation of tailing from concentrators in Pachuca agitators and Butters filter-presses, ending with precipitation of the gold by zinc-dust. The mill cost \$790,000, the railway \$93,000, and the water service \$17,000. As compared to shipping the ore to the smelters, the saving will be \$10 per ton. The cost of "ore production" is \$1.51, and of development \$9.51 per ton, the average being \$4.89 per ton. In regard to ore reserves, we quote from Mr. Mackenzie's statement:

"Excepting in the course of exploratory work, no ore has been extracted from your property below a depth of 400 ft., yet the property has yielded over \$15,000,000. The total ore produced averaged \$73.48 per ton. Owing to the short term of leases and the policy adopted by the lessees of gouging after the high-grade ore only, large quantities of low grade were purposely left; and in their haste a large proportion of high grade was overlooked, and in some cases was left for pillars. It is impossible to measure the ore remaining without driving numerous cross-cuts in the foot and hanging, which would be of little use in the extraction of ore; and not until stoping on a large scale has been carried on for several months can reliable estimates of reserve ore be made.

From the surface to a depth of 400 ft. large blocks of promising territory still remain unexplored, and from the tonnage and value of ore actually exposed, and the past performance of the stopes in the different properties, based on the experience of stoping operations in the Combination mine, it is safe to predict that your property, from the surface to a depth of 400 ft., will produce at least as much as has already been extracted, namely \$15,000,000. Below the 400-ft. point results have been very satisfactory. On the Mohawk a winze on the main orebody shows continuous high-grade ore for over 150 ft. on the dip of the vein, and has an average width of about 7 ft. All ore extracted from this winze, amounting to 535 dry tons, was shipped to the sampling works without any sorting whatever, and con-

tained an average value of \$124.72 per ton. From the bottom of this winze about 100 ft. of drifting shows average values equally as good for the full width of the drift, with both faces still in good ore. On the 600-ft. level a cross-cut proves this same body of ore to be 20 ft. wide, and although only a few inches show high grade, a 50.5-ton shipment taken as a sample from the width of 24 ft. across the vein gave returns of \$31.42 per ton."

CONSOLIDATED MINING & SMELTING CO. OF CANADA.

YEAR ENDING JUNE 30, 1908.

Metal Produced.	Quantity.	Gross Value.	%.
Gold	121,380*	\$2,488,289	45.85
Silver	2,224,888*	1,288,992	23.74

Total Smelted 318,406

*Ounces. †Pounds.

This company's mines comprise the War Eagle, Centre Star, Idaho, and Enterprise, at Rossland. The smelter is at Trail. The enterprise is controlled by the Canadian Pacific Railway.

SOUTH KALGURLI GOLD MINES.

In 1908 the mining profit was £41,166 from the treatment of 105,169 tons of ore of an average assay of 6½ dwt. Two dividends of 6d. each were paid and £5500 written off old development account, leaving, including balance from last year, £619 to be carried forward. The ore reserves blocked out on three sides are 121,868 tons, of an estimated average value of 6.97 dwt. per ton; probable ore on September 30 last, 95,897 tons, of an estimated average value of 6.13 dwt., the increase during the year being 10,829 tons of blocked-out ore and 22,370 tons of probable ore. The liquid assets consist of cash, high-class investments, gold in transit, to the value of £70,000, and all the new plant is paid for.

At the 1500-ft. level, at a distance of 359 ft. from the main shaft in the west cross-cut, a body of ore 14 ft. wide was passed through, averaging 4 dwt. per ton. There are thus three, if not four, distinct orebodies lying to the west of what is termed the Lake View lode. There is a run of highly payable ore at 1000 ft., and large orebodies are being opened at 1200 and 1500 ft. Discovery of rich ore has recently been made in the Lake View mine at a depth of 1900 ft., and another in the Great Boulder Perseverance, at a depth of 1750 ft. The company's prospects of proving the deep ground to be payable seem to be most encouraging. The result of the year's work was extremely satisfactory, considering the low value of the ore worked. A fair profit has been made, and more ore has been developed than had been mined. The discoveries at the 1000 and 1200-ft. levels have been so remarkable, and the indications on the 1500-ft. level are so encouraging that general interest in deep-sinking has been awakened among the mining companies throughout the district.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

SAFETY DEVICE FOR MINE SKIPS, CAGES, ETC.—No. 902,694. James Spry, East Rand, Transvaal.

In a safety device of the nature indicated, the combination with the vehicle and winding rope, of a catch gear which is adapted on the breaking of the winding rope to engage an obstruction in the shaft, a brake gear carried by the vehicle, a buffer gear connected with the catch gear, and a connection between the buffer gear and brake gear for operating the brake gear and gradually arresting the movement of the vehicle.

CYANIDE-TANK.—No. 894,254. Ralph S. Browne, Alameda, California.

No. 894,254.

No. 902,703.

In a tank for cyanide solution purposes, the combination with a tank of a series of pockets in the bottom of the tank, an air lift in each pocket, and a pipe extending from the air lift to a point near the top of the tank.

SAFETY BRAKE MECHANISM FOR MINE-CAGES AND THE LIKE.—No. 902,703. Henry A. Walker, Johannesburg, Transvaal.

Safety brake mechanism such as described comprising a vehicle, guiding means therefor, a frame pivoted to said vehicle, means attached to said frame for suspending the vehicle, a shaft revolvably supported by said frame, friction wheels fixed to said shaft and adapted to have contact with the guides when the vehicle is unsupported, a worm on said shaft, a worm wheel in gear with said worm, a second shaft moved by said worm wheel, a beam fixed to the second shaft on the opposite side of the guides to the friction wheels, and brake members pivoted to the vehicle and adapted to be moved by the beam into contact with the guides on the opposite sides to the friction wheels, as set forth.

FEEDING DEVICE FOR ORE-CONCENTRATORS.—No. 895,075. Emil Delster, Fort Wayne, Indiana.

No. 895,075.

No. 909,292.

In apparatus of the class described, a reciprocating table; a feed box in connection with the table, having a feed chamber and settling chamber which have communication at the forward end of the former, the feed chamber having discharge openings which extend through the bottom of the box, and the settling chamber having a shoal at its forward end and a dam at its rear end, and having also a discharge

opening at its forward end adjacent the shoal, and a waste launder having communication with the settling chamber at its rear end adapted to receive the overflow therefrom which passes over the adjacent dam, and being adapted also to convey the same away from the table.

TUBE-MILL.—No. 909,292. Harry W. Hardinge, New York.

The combination with a rotating tube-mill having a tubular trunnion opening into the same, of a tubular member secured on the end of the trunnion and in line therewith, a spiral scoop removably secured to the tubular member, having an aperture in its contiguous side wall in register with the interior of the tubular member and having a similar aperture in the opposite side wall, and a closure removably secured over the last-mentioned aperture, as set forth.

TRAMWAY LOADING DEVICE.—No. 910,499. Charles A. Case, New York.

The combination of an aerial tramway, a bucket propelled by a hauling rope of said tramway, a loading hopper supported on tracks adjacent to said tramway, a shaft that can oscillate about and move along its axial line supported on the loading hopper, an arm extending from said shaft, a roller journaled on the bucket in the path of said arm, a second arm extending from said shaft, a wedge located in the path of the second arm to engage therewith and thereby disengage the first arm and the roller on the bucket.

EXCAVATING AND LOADING MACHINE.—No. 909,982. Josephus Bingaman, Garnett, Kansas.

The combination of a wheeled frame, a tilting beam pivoted thereon and provided at its front end with an implement and at its rear end with a segmental rack, a standard mounted on the frame at the rear, a crank shaft carried in bearings on the standard and having thereon a pinion in mesh with the rack, and a detent slidable up and down on the standard and normally engaging the pinion at its upper end and having an offset foot piece at its lower end, for the purpose stated.

MAGNETIC ORE-SEPARATOR.—No. 882,158. Richard R. Moffatt, New York.

In a magnetic ore separator, a central yoke standard having an aperture, two sets of upper and lower poles arranged on opposite sides of the central yoke standard, upper and lower core pieces extending laterally from both sides of said yoke standard and in magnetic circuit with the poles and yoke standard, a feed conveyor passing between the two sets of poles and through the aperture of the yoke standard, and cross conveyors intersecting the feed conveyor.

New Type of Centrifugal Pump.

A multiple-stage centrifugal pump of a new type that the makers, the American Well Works, Aurora, Ill., assert develops higher efficiency than any heretofore designed is shown in the accompanying illustration. Ordinary centrifugals, as made by the American Well Works, have as their leading characteristic an impeller machined on both sides and edges to the exact size of the volute, with a closely adjusted cut-off at the entrance of the discharge pipe. These features make it impossible for water to pass the outlet and be re-pumped, as the clearance between the impeller and the casing is only about one sixty-fourth of an inch, and this forms a seal against the passage of water. Another feature of these pumps is that the intake and discharge is by long pipe bends, so constructed that no sudden change in direction of the water occurs when passing through the pump, thus reducing friction to a minimum.

In the multiple-stage pumps, the stages are placed close together, to shorten the shaft. The connections between the stages, however, are large pipe-bends of increasing diameter and radius, so designed that a constant expansion is allowed to the flow without sudden change in direction, which reduces the skin-friction to a minimum. The single-stage

types of these pumps operate against total heads up to 125 ft., the two-stage up to 250 ft., the four-stage up to 500 ft., with corresponding increase in heads for additional stages. Efficiencies of 60 to 80% are claimed for these pumps, depending upon the size and working conditions. A recent test of a 3-in., 4-stage centrifugal of this design, pumping from an inclosed pit, and therefore not operating under the most favorable conditions, delivered 460 gal. of water per minute to a height of 440 ft., and maintained an average efficiency of 65%. This pump was designed to deliver only 280 gal. per minute. It is claimed that the ability of these pumps to operate against high heads especially adapts them for mine pumping and for fire-protection service. All bearings in the water-end of the shaft are fitted with automatic hydraulic lubricators, and they therefore require little attention when in operation.

ASBESTOS WOOD, an invention of Charles L. Norton, of the Massachusetts Institute of Technology, is a valuable substitute for wood in construction requiring a fireproof or non-conducting substance. It is claimed that it is harder than ordinary wood, and has a transverse strength two-thirds as great. It may be worked with ordinary wood-working tools, and will take paint or varnish readily. Its fire-proof and resistant qualities have been amply proved by experiment. The H. W. Johns-Manville Co., New York, has put asbestos wood on the market in the form of sheets, ridge rolls, shingles, and is prepared to furnish it in any special shapes or sizes.

The WOOD DRILL WORKS, Paterson, N. J., has issued a 12-page booklet entitled Wood Rock Drills, giving description of the machines, showing their adaptability to tunnel driving, drilling in concrete, and open-cut work; with detailed costs in driving the Tieton Tunnel of the U. S. Reclamation Service at North Yakima, Washington. The booklet is printed in three colors and can be obtained at any of the company's offices in the United States, Mexico, and Canada.

Publications Received.

Any of the books noticed in these columns are for sale by or can be procured from the MINING AND SCIENTIFIC PRESS.

THE STEAM TURBINE: A PRACTICAL AND THEORETICAL TREATISE FOR ENGINEERS AND DESIGNERS. By James Ambrose Moyer. 8vo., pp: 379, ill. 225, index. New York. John Wiley & Sons. 1908. Price \$4 net.

The steam turbine has reached such a state of efficiency that in a few years it will probably replace reciprocating engines in all large electro-generating power-plants, and even small plants, especially those using fuel gas as motive fluid, will probably outclass the old form of steam engine. The treatise prepared by Mr. Moyer is admirable. It assumes a knowledge of the fundamentals of physics, from which starting point the subject is amplified so as to give a thorough understanding of the principles of the turbine engine. It would be difficult to find anywhere a clearer exposition of the elements of the theory of heat than that given in this book. The theory of nozzle and blade-design are worked out in great detail, the mathematical analysis being elaborate, but not calling for the use of the calculus. It is eminently a book for the designer, and equally valuable

for one having the responsibility of operating and maintaining turbine equipment. As engineer for Westinghouse, Church, Kerr & Co., in charge of turbine designing, the author is able to speak with authority on this subject.

MANUAL OF PRACTICAL ASSAYING. By the late H. Van F. Furman; revised by William D. Pardoe. 6th ed. pp. 506. New York. John Wiley & Sons. 1908. Price \$3 net.

Furman's 'Assaying' has been so long recognized as a necessary part of every laboratory equipment as to need no comment other than to announce that the new edition is not a mere re-print from old plates. The chapters on zinc, water, and coal analyses have been re-written, and improvements in old methods noted. Chapters have also been added on the assay of telluride ores, tungsten, molybdenum, and vanadium.

THE COPPER RESOURCES OF CALIFORNIA. Compiled by the California State Mining Bureau. Bulletin No. 50. Sacramento. 1908. Price, \$1.20.

This is a guidebook to localities where copper is found in California, and to companies owning copper mines. Of geology the work fortunately attempts to give little, and it refrains from offering a semblance of commercial data concerning the properties mentioned. It is profusely illustrated, and accompanied with many maps.

A HAND-BOOK OF BRITISH COLUMBIA. Bulletin No. 23 of the Bureau of Provincial Information.

The contents are quite general, and comprise information for miners, agriculturists, fruit growers, and manufacturers as to the great possibilities for development in the Province.

NEW BRITISH COLUMBIA is the title of Bulletin No. 22, issued by the same Bureau.

There are 100 pages of description of the undeveloped areas of the great central and northern interior of British Columbia, a region with an obviously rich future before it.

MAGNETITE DEPOSITS OF THE CORNWALL TYPE IN PENNSYLVANIA. By Arthur C. Spencer. Bulletin No. 359, U. S. Geological Survey.

GEOLOGY OF THE SEWARD PENINSULA TIN DEPOSITS, ALASKA. By Adolph Knopf. Bulletin No. 358, U. S. Geological Survey.

GEOLOGY OF THE TAYLOESVILLE REGION, CALIFORNIA. By J. S. Diller. Bulletin No. 353, U. S. Geological Survey.

EDITORIAL.

GOLDFIELD is the place selected for the next annual convention of the American Mining Congress. This selection meets with general approval and ought to ensure a large attendance. We hope that while it may attract deserved attention to a notable mining centre, no attempt to boost wild-cat stocks will be countenanced by those in control of the Congress.

STRONG effort is being made to get a suitable appropriation from Congress for the Alaska Road Commission. This deserves the support of every Congressman. No better national investment can be made at this time. The main obstacle to the development of the country is the high cost of transportation, due to the difficulty of access to the mining camps. The Road Commission is doing splendid work under Major W. P. Richardson: it deserves enthusiastic support.

IT IS reported that the investigating committee appointed by the Governor of New York for examining the methods of the stock exchanges, has ascertained that the daily quotations of the so-called Metal Exchange have no significance, being merely averages deduced by three men from the scant information available to them concerning the prices at which sales have been made. This fact has long been known, as has also the fact that the metal prices furnished to the daily press are meaningless to those who know, and misleading to those who do not.

FROM the latest information concerning the Italian earthquake it is learned that 120,000 human beings were killed and \$20,000,000 worth of property destroyed. In the first shock as many as 60,000 were killed in Messina alone, and 35,000 at Reggio. The first series of shocks lasted 12 minutes and thirty more followed in the succeeding three hours. For purpose of comparison it may be stated that the San Francisco earthquake lasted 65 seconds and caused a loss of life in the region affected of about 1000 persons, together with a destruction of property valued at \$500,000,000.

AMONG the investments entered in the inventory of the estate left by Quiney A. Shaw are several blocks of stocks rated as "having no value"; they include Fernando Mining Company, Marysville Dredging Company, New England Exploration Company, San Luis Valley Land and Mining Company, Smuggler Union Mining Company, and Yedras Mining Company. Among the valuable assets are 5500 shares of Calumet & Hecla, appraised at \$600 per share, or \$3,300,000, and 295,000 United

States Government 4s. at \$122, making \$481,900. Mr. Shaw has been called the richest man in New England. He did not control interests as vast as several others, but the test of wealth is in the liquidation.

IT IS probable that the Ways and Means Committee, now preparing a new tariff schedule, will reduce the duty on pig lead from $2\frac{1}{8}$ cents per pound to $1\frac{1}{2}$ cents. At the present time the London price ranges from $1\frac{1}{4}$ to $1\frac{1}{2}$ cents lower than the domestic quotation, therefore a reduction such as is contemplated will bring the price to a basis just above the point favoring importation. So far the protest against a decrease in the lead tariff has come from the miners rather than the smelters; this is not remarkable, for, of course, the burden of the lower price for lead will be immediately distributed among the ore producers, the smelter charges being deducted from the value of the metal content. Smelters not themselves engaged in lead mining will not suffer, except in so far as the lower price curtails ore production.

APPARENTLY our friends of the American Mining Congress are doomed to another disappointment. It now seems likely that the Senate will fail to act upon the bill for a Bureau of Mines at this session. Should this happen, the present bill will be killed and a fresh start must be made next year. While the excuse given for not acting, is the crowded condition of the calendar and the necessity for passing the regular appropriation bills, the real opposition comes from Senator Henry M. Teller, who, in this case, represents a reactionary Western sentiment developed by friction with the Forest Service. With him are a few Eastern senators who want no more investigations or investigating bureaus because they "hurt business". It is, of course, true that a Mining Bureau may be innocuous or even harmful as well as helpful, but the bill now before the Senate has been carefully considered, is simple in outline, and provides for an agency likely to be of large service to the mining industry. It deserves a better fate than to be smothered through senatorial courtesy during the closing days of a short session.

MISUSE of titular prefixes is exemplified by a circular letter issued in San Francisco by the Commonwealth Club, announcing that "Dr. James Bryce" is to deliver an address at a forthcoming meeting. James Bryce, the Ambassador of Great Britain to the United States, is known in his own country as the Right Honourable James Bryce, because he is a member of the Privy Council and in America he is known as Mr. James Bryce, the British prefixes of courtesy being without meaning in a democracy. But "Dr. James Bryce" leaves it uncertain whether he is a dentist with diplomatic instincts or a chiropodist of scientific attainments. Speaking seriously, most of us do not associate Mr. Bryce of 'The American Commonwealth' with a doctorate, and the fact of his having been so honored is of no particular consequence, for he honored the grantor uni-

versity. The use of the title of Doctor for others than physicians has become a question of taste; more particularly, of want of taste.

ON FEBRUARY 1 the National Railways of Mexico formally absorbed the Mexican Central, increasing the permanent way under control of the Government to 7012 miles. The matter is significant as indicating the practical success that has attended the system of governmental administration of railways in Mexico. Official corruption is prevented by a complete severance of railroad management from the political mechanism of the Republic. The Mexican Central, for example, continues as a separate corporation, and is operated by the National Railways of Mexico by virtue of government ownership of 70 per cent of the Mexican Central stock. The management continues unchanged, and promotion for merit is observed as it is by well-organized railroad corporations in the United States. The National railways are subject to the rulings of the Railway Commission, a body representing both the private and government-controlled lines, that is vested with absolute authority in the fixing of rates. The Mexican system permits of no discrimination, no graft by favored shippers to be divided with conniving officials, and the adjustment of rates is made to insure profit to the transportation line and to benefit the shipper. It is interesting to note that, as Mexico is committed in principle to a protective tariff policy, the adjustment of freight rates has been used as an instrument to facilitate the same purpose.

Copper Statistics.

Copper statistics have been issued from two sources: the Copper Producers' Association has made its first report, through its secretary, Mr. L. C. Graton, showing that the stock of marketable copper on hand in the United States on January 1 was 122,357,266 pounds, the production in the United States during January was 112,135,200 pounds, while the deliveries for consumption and export during the same month were 90,362,421, leaving a stock on hand, on February 1, amounting to 144,130,045 pounds. This is not cheerful from the mine operator's point of view, but it confirms our understanding that the mining companies have found difficulty in disposing of their metal. According to the Bureau of Statistics, in the Department of Commerce and Labor, the value of copper and manufactures of copper exported during December was \$6,958,710, which compares with \$11,337,544 in the corresponding month of the year previous. The total copper exported during 1908 amounted to \$90,555,503, as compared to \$100,800,355 in 1907 and \$89,013,011 in 1906. Furthermore, the monthly report issued by James Lewis & Sons, Liverpool, shows a total stock in England and France of 45,535 tons of copper on February 1, 1909, as against 13,360 tons a year ago, and 8691 tons in 1907. The total visible supply available for European necessities is given as 52,935 tons as against 20,660 tons a year ago. No wonder the copper market is weak.

Tartuffe in Colorado.

Humor is requisite in viewing some of the efforts to stop fraud in mining; only an appreciation of the absurdity of the pose adopted by certain pseudo-reformers, themselves the worst culprits, can deter the observer from making savage comment. Insincerity is provoking, and the most objectionable is that of the man who plays with public sentiment. We are reminded of a State official who makes a great fuss about putting down fraud with his right hand, while his left is doing service for corruptionists; of men who pose as defenders of the common good while acting in behalf of predatory powers. California is blighted with several performers of this type, and if the reader cannot identify them even though vaguely described, he is ill informed. But local politics and local finance are such an *olla podrida* that we shall not at this time enquire further, a more amusing illustration having been offered in Colorado. In the city of Denver there is a paper called *The Mining Investor*, edited by a suave and capable gentleman, who poses as the defender of the guileless investor, meaning thereby the ignorant gambler in mining stocks of the kind that are peddled with an announcement that "the price will be raised to 15 cents on Friday." Not content, however, with the support of those who advertise such lures, this *amicus curiae* to the supposititious mining investor undertakes to castigate fraudulent promotions and irresponsible financial schemes; and yet, on closer investigation, the chief apparent difference between the promoter applauded and the promoter attacked, between the one who receives a bow and the one who is slapped in the face, is that the one does, and the other does not, advertise in *The Mining Investor*. In other words, the publisher of that financial mentor to simpletons is careful not to let his right hand know what his left hand doeth; it is an extreme form of mental detachment. But this is not all. In the last issue of this peculiar journal we are amused to see an attack upon the American Mining Congress because, while making a show of fighting fraud in mining, it has sheltered two gentlemen "conspicuously inefficient or unfair in their dealings with the public," in plain words, two promoters of shady repute. Now whether these gentlemen merit this description or not, the point of the episode is the humor if it. Here is the *Investor* devoting a couple of pages of verbosity to protest against the inconsistency of the Mining Congress in honoring the exponents of the very practices against which the Congress is fighting. This is too funny! The editor of the *Investor* lives in a conservatory full of fungi and ought not like a small boy to play with catapults. For, turning to another page of the same issue we find the advertisement of a Mr. Davis who "will divide more than \$60,000,000" to those who buy shares from him; on another page you are offered stock at 3 cents that will soon go to \$1; on another a Mr. Kennedy who is sacking \$150 ore gives you the chance to buy stock at 15 cents per share, and you can have five months time to pay for it; on another, a fortune in Nevada petroleum awaits you, although

the recent report of the Geological Survey gives information to the contrary. And the gentleman who derives his revenue from advertising such schemes is the one who takes it upon himself to criticize the Mining Congress. He must wash his own hands first with antiseptic soap. Fraud is bad; humbug is worse.

Mining and Metallurgical Society.

From the presidential address delivered by Mr. H. S. Munroe at the annual meeting of the Mining and Metallurgical Society of America, it appears that good progress is being made by the new organization. As yet, however, the activities of the Society have been restricted to the meetings of two local sections, one at New York and the other in San Francisco. Each has done some useful work, and hopes to do more, but it has already been demonstrated that the rules which suit the New York division do not please the co-ordinate branch of the Society in San Francisco. The latter asks for more latitude, verging upon local autonomy, strengthened by affiliation with the headquarters division on the other side of the continent. Undoubtedly the gentlemen in San Francisco have broken some rules in the making of which they had nothing to say, and they require disciplining in the interest of the Society as a whole, but they ought to be gently treated, because their purpose was that for which the Society was formed, and the section ought to be forgiven for declining to accept the status of a younger brother. Joking apart, the Society will make a blunder if it become too much identified with the New York group; for instance, one of the gentlemen on Manhattan island remarked that "the New York section, which was the first section to be organized, has found no difficulty in complying with the rules prescribed by the Council, and, inasmuch as the rules have been thus demonstrated to be workable, there is no reason why other sections should not comply with them and follow the same lines as the New York section." This is amusing, for it must be remembered that the executive committee of the Society consists of the New York men who formulated the rules; naturally they like them, while the men in San Francisco, who had nothing to do with the devising of such rules, desire to amend them. From the thoughtless observation just quoted it is pleasing to refer to the true note sounded by Mr. H. M. Chance, the founder of the Society, who "advocated the allowance of latitude to the local sections wherever it did not interfere with the spirit of the organization as a whole." A little sense of humor will prevent trouble. Long ago California had a historic scientific society "on the Stanislaus", but that was in the foot-hills of the Sierras; we have moved to the placid Bay of San Francisco since then and no longer use "chunks of Old Red Sandstone" in a lethal way. It is well to emphasize the fact that the United States has several centres of intellectual and industrial activity; New York is not to America as London is to England or Paris to France; there are Boston, Washington, Philadelphia, Chicago, Denver, and other cities. As one of the others, San Francisco begs leave to point

out that the time has passed when professional men living on the frontier have to go to New York or Boston to get physical or mental nourishment, psychological or financial stimulus. The frontier has vanished; it is somewhere near Guam, and we who live on this side of the continent find it pleasant but no longer necessary to visit New York at frequent intervals. As regards the new Society, the members in the West are glad that the headquarters should be at New York, and also that the officers should be residents of that superb city, but they are not prepared to be considered as the small boy of the family.

Yukon Gold.

On another page we publish the major portion of a letter sent recently by the president of the Yukon Gold Company to the shareholders. This letter, presumably, is a substitute for an interim report; but it is an inadequate substitute. While interesting, the information given is too general; it has the character of an interview in the daily press rather than a statement meant for partners in an important enterprise. Looking at the report from the standpoint of a shareholder—a position, needless to say, we do *not* occupy—it would seem proper to expect a clear statement of the salient facts: cost of mining, yield of gold, results of experimental work, expenditure on the ditch, cost of thawing, money expended in new plant. No reference is made to the fiasco of last March, when Mr. Thomas W. Lawson of Boston played the fool with the Yukon Gold, nor is any account given of the money raised by the filibustering operations in which Mr. W. B. Thompson's services were utilized. At that time we criticized the entire financial scheme, more particularly the attempt to inflate the value of the stock by means of wild statements advertised by Lawson. We showed then that according to the reports available, Yukon Gold was worth about \$3 per share; we have found no reason to change this appraisal, although better able to appreciate the general accuracy of the estimates of the engineers who made the reports. Further information concerning the character of the operations at Dawson has increased our good opinion of the skill and energy shown by Messrs. O. B. Perry, C. A. Thomas, A. N. C. Treadgold, and their co-adjutors in the construction and development that will make the Yukon Gold a great gold mine, but nothing has transpired to alter our conclusion that the Yukon Gold was wretchedly financed. In the Guggenheim Exploration Company's annual report the Yukon Gold is put down for \$8,222,062 as against \$8,222,109 last year, from which it is to be inferred that this asset has diminished \$47 in value. Apparently it is thought proper for presidents and directors to go through the motions of giving information to the shareholders for whom they act as trustees, instead of treating them as partners. Imagine Mr. S. R. Guggenheim sending such a vague epistle to a member of his firm. Shareholders are partners; directors are trustees; the sooner these relations are recognized the better for the mining industry.

BY THE WAY.

On the centenary of Lincoln and Darwin, February 12, an address was delivered by Henry Fairfield Osborn at Columbia University, New York. He said, in part:

Widely different in their lives, Darwin and Lincoln were yet alike in simplicity of character and of language, in love of truth, in abhorrence of slavery, and especially in unconsciousness of their power. Both were at a loss to understand their influence over other men. "I am nothing, and truth is everything," once wrote Lincoln. "With such moderate abilities as I possess," wrote Darwin, in concluding his autobiography, "it is truly surprising that I should have influenced to a considerable extent the belief of scientific men on some important points. My success as a man of science has been determined, as far as I can judge, by complex and diversified mental qualities and conditions. Of these, the most important have been the love of science, unbounded patience in long reflecting over any subject, industry in observing and collecting facts, a fair share of invention, as well as of common sense."

Lincoln's greatest single act was his death blow to slavery. Man had been fighting for centuries for his freedom—in labor, in government, in religion, and in mind. It is certainly notable that the final victory for bodily liberty was won during the very years which witnessed the final victory for mental liberty. I do not see that Darwin's supreme service to his fellow men was his demonstration of evolution—man could have lived on quite as happily, and perhaps more morally, under the old notion that he was specially made in the image of his maker. Darwin's supreme service was that he won for man absolute freedom in the study of the laws of nature; he literally fulfilled the saying of St. John, "Ye shall know the truth, and the truth shall make you free."

It is difficult for the college student in this day of liberty, if not of license, to realize that, in the words of Lowell: "We breathe cheaply in the common air thoughts that great hearts once broke for."

When, in 1844, Darwin communicated to the botanist Hooker, under the promise of secrecy, his outline of evolution, he well knew he opprobrium it would bring, for he subsequently added (1846): "When my notes are published, I shall fall infinitely low in the opinion of all sound naturalists—so this is my prospect for the future."

Where his great predecessors Buffon and Lamarck had failed, Darwin won through his unparalleled genius as an observer and reasoner, through the absolutely irresistible force of the facts he had assembled, and through the simplicity of his presentation. Lacking the literary graces of his grandfather Erasmus Darwin and the obscurity of Spencer, Darwin was understood by everyone, as everyone could understand Lincoln. It is true the cause was immediately championed by able men, but victory was gained not by the vehement and radical Haeckel, nor yet by the masterly fighter Huxley, but through the resistless power of truth as Darwin saw it and presented it. It

was not a denial, as had been the great skeptical movement of the end of the eighteenth century, but an affirmation. Darwin was not destroying; yet at the time good and honest men trembled as if passing through an earthquake, for in the whole history of human thought there had been no such cataclysm.

In July 1837 he began his notes on the transmutation of species, based on purely Baconian principles, on the rigid collection of facts which would bear in any way on the variation of animals and plants under domestication and in nature. Rare as was his reasoning power, his powers of observation were of a still more unique order. He persistently and doggedly followed every clue; he noticed little things which escaped others; he always noted exceptions, and at once jotted down facts opposed to his theories.

The three memorable features of Darwin's greatest work, 'The Origin of Species', are, that he was 21 years in preparing it; that, although by 1844 he was a strongly convinced evolutionist and natural selectionist, he kept on with his observations for 15 years, and the volume even then would have been still longer postponed but for a wonderful coincidence, which constitutes the third and not the least memorable feature. This coincidence was that Wallace had also become an evolutionist, and had also discovered the principle of natural selection through reading the same essay of Malthus which had brought Darwin to a solution. It is further remarkable that of all persons Wallace selected Darwin as the one to whom to send his paper. It was then, through the persuasion of the great botanist Hooker, who had known Darwin's views for 13 years, that these independent discoveries were published jointly on July 1, 1858. All the finest points of Darwin's personal character were displayed at this time; in fact, the entire Darwin-Wallace history up to and including Wallace's noble and self-depreciatory tribute to Darwin on July 1 of last summer, is one of the brightest chapters in the history of science.

There is no denying that there is today a wide reaction against the central feature of Darwin's thought. Now, on this centenary, when we are honoring Darwin, many may ask, exactly what is Darwinism? Failure to know leads some to doubt, others to predict a decline, especially where "the wish is father to the thought." Nothing could be less true than to say that there is the least abatement in the force of the main teaching of this great leader, namely, of the evolutionary law of the universe. The vitality of this idea is shown by its invasion of the physical world. Again, Darwinism is the sum of Darwin's observations on earth structure, on plants, animals, and man.

This vast body of truth and of interpretation still so far surpasses that brought forward by any other observer of nature, and these facts and interpretations are so far confirmed that they have become the very foundation stones of modern biology and geology. Finally, looking at Darwinism as the sum of his generalizations as to the processes of evolution, we again find a vast body of well established laws which are daily becoming more evident.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HIRAM W. HIXON is traveling in Italy.

JOHN M. BOUTWELL is at Bisbee, Arizona.

GELASIO CAETANI is still at Treadwell, Alaska.

W. A. FARISH spent last week at Los Angeles.

H. FOSTER BAIN was in San Francisco this week.

A. H. DOUGLAS has gone to Matagalpa, Nicaragua.

EVERARD ARNOLD has returned from Mexico to Ely, Nevada.

ALFRED VON DER ROPP is on his way to Geneva, Switzerland.

EDMOND N. SKINNER was married on February 4 at New York.

S. F. SHAW is examining mines in Cochise county, Arizona.

A. W. WARWICK has recovered from illness and is now at Denver.

R. V. NORRIS delivered a course of lectures on coal mining at Harvard.

PHILIP WISEMAN, superintendent of the Ray mine, at Kelvin, Arizona, was at Los Angeles.

MARK R. LAMB is now in the mining machinery department of the Allis-Chalmers Co., at Milwaukee.

GEORGE A. LONSBERRY and GEORGE KISLINGBURY, of Los Angeles, have been to the Parker district, Arizona.

W. G. ANDERSON, manager for the Iona Gold Mines at Smuggler, Colorado, is on a visit to the Eastern States and Canada.

CLYDE H. JAY, mining engineer, of Salt Lake City, is examining mines in the Monarch district, Chaffee county, Colorado.

C. G. PATTERSON has gone to Mexico, after completing a Butters installation in the mill of the Goldfield Consolidated Mines Co., Nevada.

H. H. DYER has resigned as superintendent of the Shannon Copper Co., and has opened an office as consulting mining engineer at Los Angeles.

S. B. CHRISTY and J. B. TYRRELL are among those recently chosen as corresponding members of the Council of the Institution of Mining and Metallurgy, London.

HENRY S. WASHINGTON, of Washington & Lewis, mining geologists, New York, has returned to Brazil, where he will spend three or four months in professional work in the diamond fields.

THE thirty-sixth annual dinner of the alumni of the Royal School of Mines will be held at the Hotel Cecil, London, on March 30. The chair will be taken by F. W. Rudler. Tickets can be obtained from George T. Holloway, 57 Chancery Lane, London.

A special meeting of the Pacific Coast Section of the Mining and Metallurgical Society of America was held at the Pacific Union Club, San Francisco, on the evening of February 13. Those present included S. B. Christy, Charles Butters, F. W. Bradley, M. L. Requa, W. H. Shockley, Ernest A. Hersam, and T. A. Rickard.

The presidential address of Mr. Henry S. Munroe having been read, together with correspondence between the local Secretary and the Secretary in New York, F. W. Bradley moved that: Whereas the meetings of the Section having been found enjoyable and useful, and it is desirable to continue them under the name of the Society, and whereas it has been found impracticable to fit the proceedings to the rules laid down in New York, therefore, it is advisable to develop rules suited to local conditions, while keeping in touch with the central office in New York.

This was seconded by Charles Butters and carried unanimously.

T. A. Rickard moved that every qualified applicant to membership shall be balloted for and elected by the members belonging to the section in which the applicant lives.

Seconded by W. H. Shockley and carried unanimously.

E. A. Hersam moved that the local dues be \$5 per annum.

Seconded by M. L. Requa and carried unanimously.

It was arranged to hold the next meeting on March 13, at the Key Route Inn, Oakland. The arrangements for the dinner were placed in the hands of Charles Butters, to whom members should write as soon as they know whether they will be able to attend.

Bert Peterson.

In our last issue a brief mention was made of the death of Bert Peterson, the manager of the El Rayo mines of Santa Barbara, Chihuahua, Mexico. His mining experience was confined to Mexico, where he went some twenty years ago from his home at Paterson, New Jersey, at the age of twenty-one.

His first work was in and around the Guggenheim lead properties at Monterrey. He next became manager of the Sierra Mojada mines in Coahuila. In 1899, he was made general manager of the Grand Central at Minas Prietas, Sonora, this being one of the properties originally brought out by the London Exploration Co. In 1901, Bert Peterson was offered the general management of the property of the El Oro Mining & Railway Co. at El Oro, but as he had then become personally interested in a number of mining properties he decided to give his attention to their further development rather than to continue professional work. One of the properties in which he was personally interested is now known as the Ajuchitlan and is situated in the State of Queretaro. Another, now known as the El Rayo mines, is situated near Santa Barbara, Chihuahua. Peterson had a long hard struggle in putting these properties on their feet and did not succeed in doing this until after a sale of the El Rayo had been made in New York. As a condition of the sale, he was obliged to take over the management of the El Rayo property and become responsible for all the statements he had made regarding it. Thus Peterson was enabled to secure sufficient funds to equip the Ajuchitlan mine, a property that recently paid its first dividend and promises to develop into an important gold mine.

At the time of his death Peterson had almost pulled the El Rayo property through its experimental metallurgical stage, and he was so confident of 'making good' as to all his predictions regarding it that he was planning to retire from the management next April. The El Rayo operations, however, had called forth so much hard work and worry that Peterson's health became seriously impaired and his vitality undermined. Against the advice of his family, who knew that his health was being injured, he persisted in his work and made a brave fight for his professional name. It may indeed be truthfully said that he gave up his life in order to maintain his professional reputation. He had promised his associates and friends that he would redeem all the promises he had made regarding the El Rayo property and they could not deter him from carrying out this self-imposed task. Last December he sent his wife and 3-year old boy to his home in Philadelphia for the Christmas vacation. Although ill, he refused to accompany them on the plea that the El Rayo needed his constant attention. On their return, Peterson got up from his sick bed to meet them at El Paso, and in doing so rode on horseback some 12 miles in order to catch the train at Santa Barbara. On his return to the mine he was compelled to go back to bed and it was only as the result of the constant urging of his family and friends that he reluctantly consented to proceed to Los Angeles for proper care and treatment. His sickness was diagnosed as typhoid fever, the crisis of which he did not survive because of his worn-out condition. He was well and favorably known throughout Mexico and leaves many friends, whose deepest sympathy goes out to his wife and child.

General Mining News.

ALASKA.

Alaska Venus Mining Co., of Spokane, capitalized for \$2,000,000, has been incorporated by Frederic Wright, Frank Vay, and Joseph Parker. The property consists of four claims lying near the water 10 miles south of Juneau. Wright says there is an 8-ft. vein 4500 ft. long on the claims, and that it carries good gold values. An adit has been driven 137 ft. on the vein and the surface has been stripped, showing uniform values. A small stamp-mill will be installed this spring, to be run by water from a snow-fed stream which crosses the property.

(Special Correspondence).—Recent arrivals from Innoko and Kuskokwim report that the scarcity of provisions have forced many to leave the district for Nome, but about 150 men have remained for the winter at Innoko, and have been staking out claims in the region around Ophir and Little creeks.—The people of Innoko City, at the mouth of the Ditna river, are for the most part moving to Diskakat.—There are good summer diggings at Gaines creek, but the operators have been much troubled by water.—The annual report of the Mayor of Hot Springs shows that to date there have been built 165 miles of wagon-road, 383 miles of sleigh-road, and 241 miles of trail. The Mayor speaks very highly of the agricultural possibilities of Alaska.—Owing to the large increase in business the Signal Corps is now stringing a second wire from Fairbanks to Valdez.—A well-defined vein is being prospected by D. H. Cameron on Chatham and Bedrock creeks at the head of Cleary creek.—Quartz discoveries in the Tanana valley have caused much interest to the inhabitants of Fairbanks, several samples having assayed \$24 and over.—Jerome Chute, Thomas McConnell, and R. M. Crawford have purchased the holdings of 'Red' Rogers and are bringing in an Allis-Chalmers 3-stamp mill from 'outside'.—The annual report of Wilfred B. Hoggatt, Governor of Alaska, gives the population of Alaska in judicial divisions as 9000 in the first, 10,000 in the second (with Nome as centre), and 12,000 in the third (Fairbanks) division. The native population is approximately 35,000, and there is also a floating population of six or seven thousand miners, cannery men, etc., who only come into the country in summer. Hot Springs, January 27.

ARIZONA.

GILA COUNTY.

Notwithstanding that work at the Arizona Commercial Copper property on the 700-ft. level has been necessarily delayed awaiting the installation of new pumps to handle the increased flow of water, there have been recent important underground developments. At a depth of 710 ft. in the Eureka shaft a station is being cut 36 ft. square. In cutting this station, good copper ore has been found, and cross-cutting will be started immediately. Connection is now being made between the 500 and 556-ft. levels by means of a raise which has already progressed 28 ft., and averages 6% copper for the entire width.

GRAHAM COUNTY.

The Arizona Copper Co. suffered a destructive fire during the month of January, which put the works and smelter out of business a number of days. Nevertheless the company has finished up the month with an output of 1064 tons of blister copper, which is only 300 tons less than the normal amount.

CALIFORNIA.

INYO COUNTY.

(Special Correspondence).—Senator T. L. Oddie, of Tonopah, and a syndicate of Chicago and Philadelphia capitalists have secured the Dixon water rights on the upper Kings river, and plan to construct a large power-plant to supply electricity to the mining camps of southern Nevada and numerous points in California. The projects of the

new company involve expenditures approximating \$9,000,000. It is understood that the new company will compete with the Nevada-California Power Co., supplying electricity to Goldfield, Tonopah, and other points.—The Natural Soda Products Co. is building a \$100,000 plant near the shores of Owens lake. It is ultimately intended to add two more units of the same size. R. G. Paddock is directing the work.—Reports from Greenwater are to the effect that a 60-ft. body of sulphide ore, running about 5% copper, has been encountered in the Greenwater-Death Valley mine at a depth of 1000 ft. The shaft is being sunk to the 1500-ft. level, from which point cross-cutting will be done to determine the persistence of the orebody.—At the Greenwater Central work has started on the sinking of a 2-compartment shaft. The shaft is about 250 ft. from the Greenwater-Death Valley mine and is designed to cut the orebody encountered in the latter.—At the Lida C. mine a large force of men are working and a normal output of borax is being maintained.—The 20-stamp mill at the Orange Blossom is handling 80 tons of ore per day. A large reserve of fair-grade ore has been opened up as far as the 200-ft. level.—At the Orange Blossom Extension an 8-stamp Nissen mill is handling good ore. The shaft will be carried down to the 1000-ft. level and other developments done on a similar large scale.—The Fitting mine is working 50 men and maintaining steady shipments of excellent ore. Three teams are constantly engaged hauling the ore from the mine to the railroad.

Bishop, February 13.

NEVADA COUNTY.

Official announcement is made that the Brunswick mine will resume operations, and that a perpendicular shaft will be sunk in new ground to join the old workings at a depth of about 1200 ft. The directors have elected a new president, J. W. Pew, who represents the Eastern syndicate controlling the stock. On good authority it is stated that Christopher Mallen resumes his position of superintendent and that Frank McDavitt will be promoted to the office of foreman.—Le Roy M. Clark, while developing a vein of quartz near the junction of the Red Dog and You Bet roads, came across a vein of new ore which turns out to be bauxite, the hydrous oxide of aluminum. He is said to be enquiring if he can find metallurgists to treat the new deposit.—Recently the middle parallel vein of the Marcotte mine was cut in the lower adit. When the vein was first reached it was only six inches wide, but now has increased to about six feet, and shows abundant galena. J. M. Fly is manager.

PLACER COUNTY.

The Southern Pacific is beginning construction work on another line between Roseville and Truckee, which will lower the elevation of the tracks by 1000 ft. and give a maximum grade of 1.5% instead of the present grade of 2.2%. The work will involve the driving of a six-mile tunnel, and will require about four years to complete.

SHASTA COUNTY.

The damage of the recent washout on the Balaklala spur-track connecting with the Southern Pacific at Coram, has been entirely repaired. A trestle was built by the Southern Pacific Co. to replace the fill that had been washed out, and traffic was resumed. Some of the fluxing supplies had run quite low, especially limestone. The Balaklala mine is the most extensive property in Shasta county and the smelter is the largest in California. About 500 men are at present employed at the mines and plant, and two of the furnaces are in full operation. Besides the ore from the Balaklala mines, the smelter is treating a considerable tonnage from the Shasta King mine of the Trinity Copper Co. At present the smelter is treating about 1000 tons of ore per day. Fluxes are received from numerous points in California and Nevada, and are not usually the cause of any difficulties.—Morgan Thomas has resigned his position as superintendent of the Balaklala and Shasta King mines. He will spend a few weeks on vacation.—At the Midas mine 20 stamps are working on ore from the deep

est workings, or from the Gold Hill claim. The practice of roasting tailing before cyaniding has been discontinued.

TRINITY COUNTY.

H. P. Nelson, president of the Trinity River Mining Co., announces that only a hundred feet or so are required to complete the tunnel which is to turn the course of the Trinity river at Horseshoe bend near Lewiston. At one time during the high floods the river threatened to fill the workings before they were ready, and stopped work in the face till the river fell. The tunnel will be 1450 ft. long, and 8 by 10 ft. in the clear, enabling it to carry the entire flow of the river during at least 9 months of the year. It will thereby expose a stretch of two miles of gravel for mining purposes. H. P. Nelson is president, John Lantsen vice-president, Hans Lassen treasurer, W. R. Thomas secretary, and the offices are situated in Oakland.—The Trinity Gold Mining Co. is working between 20 and 25 men. Three giants are running successfully on the body of gravel that was given a shaking-up by the big blast of a few weeks ago.—The Butler Mining Co. is using only one giant. Five men are employed. The water supply for the pipe-lines is more than ample.

TUOLUMNE COUNTY.

At the Riverside mine, operated by a Tennessee company, 12 men are employed. Ore is being extracted and milled, and adit No. 2 is being driven; preparations are also being made for installing an air-compressor and power-drills.—The Spotted Fawn is giving promise of becoming a mine. Thirty tons of ore recently milled gave returns far better than were expected, and as a result the working crew will be increased.—The mill at the Arbona mine, at Tuttletown, will soon be running night and day. At present it is in operation only during daytime, on ore from the first, second, and third levels. The crew numbers 12 men, but when the fourth level has been opened up a larger crew will be employed.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—The Geneva Extension M. M. T. & T. Co. has been organized by E. K. Cass. A group of 33 lode-mining claims in the Peru district has been obtained, and work has already been put under way. An adit is being driven to intersect the series of veins in depth, two having already been passed. The Star was a former heavy producer of silver-lead ore, and is an extension of the Revenue, which has produced over \$1,000,000. Arrangements have been made to work the mine through the Mallory adit of the Revenue.—Another contract is to be awarded about March 1 for driving the Vidler tunnel an additional 500 ft. The bore is now in 4000 ft. on this side of the range. It is understood that as soon as the weather permits, work will be put under way from the western side of the range. Progress will then be made at the rate of from 10 to 12 ft. per day, and as there only remain 2600 ft. of ground to be broken before the connection is made, the work should be completed during the present year. It is the intention of the Argentine-Montezuma M. M. & T. Co. to install an electric trolley system to transport the low-grade ores from the fields of Summit county. By the Vidler tunnel the route to the Denver smelters will be shortened by over 75 miles.—H. Davenport has taken a contract for driving the adit on the Vesper group of claims, on McClellan Mtn. The bore is now in 700 ft., two veins having been passed. No drifting has been performed, as it was considered best to intersect the Vesper vein previous to exploiting the ground.—A big force of men is being employed at the Marshall-Russell adit on Silver Mtn. The adit has now advanced 2500 ft., and from surveys the Neef vein should be reached within the next 15 or 20 ft. The company controls all the ground lying along the course of the adit for a distance of 12,000 ft. O. N. Marighugh is manager.—Work has been resumed upon the Scott property, situated on Republican Mtn. Oklun Bros., the owners, purpose running the adit for at least 200 ft. to intersect

two known veins. The Scott was a former good producer, but has been idle for the last five years.—Ore production at the Specie Payment mine on Seaton Mtn. has been suspended for a month to permit of the excavation of a station in the Two Brothers adit. At this point a hoist is to be installed, as a shaft is to be sunk 200 ft. below the adit level. This property has been sending out from 1300 to 1500 tons per month, the greater part of the product being sent to various mills for concentration. A. M. Welles, of Denver, is manager.—Report is current that the Argo M. D. T. & T. Co., owning the Newhouse 'tunnel' at Idaho

The Central Part of Colorado.

Springs, will soon start work upon the construction of a smelter with a capacity of 500 tons per day. The plant is to be built not far from the entrance of the 'tunnel' and will be run upon ores from the various mines that are being operated through that bore. What gives credence to the report is the statement that Samuel Newhouse proposes erecting smelters throughout the country that will be equipped with the Fink furnace. This would prove a great boon to the region tributary to Idaho Springs. There are several mines that could furnish from 100 to 200 tons of ore daily, notable among which are the Gem, Sun and Moon, Saratoga, and Old Town.

Georgetown, February 13.

LAKE COUNTY.

Work has been progressing for the last 9 months on the

Bald Mountain adit, at the head of California gulch, by farther advancing the old Garibaldi 'tunnel,' which had been driven and abandoned 25 years ago. The breast of the adit is now 2600 ft. from the mouth, and 780 ft. from the surface, and it is at this point that a seemingly large and valuable deposit of lead ore has been struck. The ore is galena, carrying 65% lead with a good proportion of silver, and the whole deposit is shown to be 12 ft. thick. The ore so much resembles that at the Sunday mine that there can be no doubt of the veins being the same. M. A. Nicholson, W. Morrell, G. E. Keeler, L. A. Reynolds, and Percy Hamm are the directors of the Tunnel company.

SUMMIT COUNTY.

J. Wall, dredgemaster of the *Swan*, has assembled a working crew and is repairing the boats to resume dredging by March 1.—The *Reliance* dredge, in French gulch, which has been running all through the spell of cold weather, will remain in commission for the rest of the winter, thus demonstrating the fact that dredging can be carried on in the midst of the Rocky Mountains all the year round.

TELLER COUNTY.

Grading has been started near the main shaft of the Golden Cycle Mining Co. for the mill to be erected for the

operation. According to these circulars the No. 4 tunnel has reached the walls of the vein, and it is expected that only a few feet of advance are required before ore may be broken into. A detailed report of the property accompanies each circular.—The new equipment, consisting of gasoline engine and hoist, etc., recently ordered by the Government Gulch Co., has been delivered and installed, and it is expected that development will be resumed immediately. It is the intention to sink the shaft another 100 ft. and then to explore the vein.—The long adit of the Snowstorm mine in the Mullan district has been driven to within 80 ft. of the vein. This adit is at present 3100 ft. long and is designed to reach a depth of 550 ft. below the present lowest workings. In the meantime the mine is shipping at the rate of 12,000 tons per month. The ore goes to several smelters, and a sample shipment of 500 tons has been made to the Balaklala smelter in Shasta county. There is said to be enough ore blocked out at present to allow steady shipments at the rate of 500 tons per day for the next three years.—Charles McKinnis, manager of the Caledonia mine, where a strike was made at the face of a drift on the 300-ft. level a week ago, has brought to Spokane some samples of ore, which assay from 66 to 334 oz. silver, with lead in proportion. Some of the samples are pure crystal-

The Copper Region of Lake Superior.

treatment of low-grade mine and dump ores. The mill will have a capacity of 500 tons daily and will adopt a system of dry crushing and screening before concentrating six tons into one. About 330 tons per day are being shipped from the main shaft to the Golden Cycle mill at Colorado City, no damage having been done to either shafts or levels by the so-called earthquake which recently shook up the residents of Independence and Goldfield.—A new hoist and compressor have been installed at the main shaft of the Bonnie Nell Merger Gold Mining Co. on the eastern slope of Raven hill. The 500-ft. shaft has been re-timbered to a depth of 400 ft. below the collar and a new head-frame has been erected.—The report of the United Gold Mines Co., issued by the general manager, H. McGarry, shows a balance in hand at the end of the year of over \$38,000. There are 28 sets of lessees engaged on the different properties of the companies, and the royalties received from these amounted to \$23,130. All the leases have been let with various conditions as to a necessary amount of development to be done, with the result that the whole property is in good shape.

IDAHO

SHOSHONE COUNTY

The stockholders of the Nonpareil Copper Co. have been called on to face the question of raising finances for working the property during the present season. Circulars have been mailed to each with the object of securing their co-

lized lead, others are wire silver, and others are chlorides of lead. Experts say that the ore is similar to that found in the Last Chance and the Hercules mines.—Frank Gaffney has just filed applications at Lewiston for mining claims in the Weippe district. William Gaffney and S. P. Fitzgerald are interested in the property, which they have prospected since 1907. The claims are near the 8000 acres of land recently leased for a term of 50 years to G. W. Thompson, who will spend a large amount of money in prospecting the croppings which show hematite ore in payable quantity. Several experts are coming from Duluth in April to make a thorough examination of the district for Eastern capitalists. The lease held by Thompson provides for the payment to the State of Idaho a royalty of 15c. per ton for all ore mined. The timber on the land belongs to the State.—The Great Eastern Mining Co. has just awarded a contract for 200 ft. of cross-cut work on its property on Canyon creek to tap the Cape Horn vein. The property has been extensively developed and some good ore has been opened on the No. 1 vein. When in about 500 ft. the lode was cut by a cross-cut and drifted upon 1700 ft. in an easterly direction. The cross cut now to be run is from the face of this drift.—F. H. Brownell, of New York, who succeeded Charles Sweeney as president of the Federal Mining & Smelting Co., is at Wallace looking over the properties and becoming familiar with the details bearing on the litigation between the Bunker Hill & Sullivan and the January Mining Companies.

MICHIGAN.

An examination of lode material from the 75-ft. amygdaloid bed disclosed by trenching on the lands under option to the new Baltic Exploration Co. shows all the characteristics of the Baltic lode, and there is little doubt that the northern extension of the South Range lode has been definitely ascertained.—Isle Royale's shaft on the Baltic lode is being sunk below the 110-ft. level, and will soon be deep enough to warrant investigation by cross-cutting.—North Lake has two diamond-drills going through solid rock. No. 2 drill is nearing the eastern standstone.—The Lake Co.'s shaft, 400 ft. deep, is bottomed in rich copper ground. The company is driving a drift at this depth.

The Winona mine is in good shape physically, and already is opened well ahead of immediate requirements. Operations are confined to No. 4 shaft, where driving is in progress on the fifth, sixth, seventh, and eighth levels. The shaft is approaching the tenth level. Eight machine drills are in regular service. The present showing of copper is unquestionably the best in the history of the mine, and compares very favorably with the average rock being mined in the district.—The Ojibway No. 1 shaft shows the Kearsarge lode well mineralized. The mine was cutting a plat when the lode was encountered. The cross-cut at the No. 2 shaft is in about 40 feet and will reach the lode within a week.—The Wyandot has entered the amygdaloid lode at the 700-ft. cross-cut. There is practically no copper yet showing.

KENT COUNTY.

The long distance electric power line from the Muskegon river to Grand Rapids, holds the world's record for high voltage transmission of electrical energy. This record voltage is 110,000 volts, and it is only a few years ago that the 72,000-volt pressure over this same line was the highest in the world. The wires for this high tension are suspended from steel towers 53 ft. high and 500 ft. apart. They are insulated with five large porcelain discs 10 in. diameter, which are tested to stand a pressure of half a million volts without arcing. A peculiarity of this enormous electrical pressure is to cause a static discharge from the transmission wires into the atmosphere, causing a crackling sound which can be heard for a considerable distance. In the dark this discharge can be seen as a luminous haze around any point where there is an irregularity in the copper wire.

MONTANA.**LEWIS AND CLARK COUNTY.**

The new electrolytic plant of the Elkhorn Electrometals Co. has been started, but so far sufficient time has not elapsed to gauge the efficiency of the process. The plant is the first one of its kind of commercial size to be erected in the country.

MISSOULA COUNTY.

M. B. Gray, of Trout Creek, who has been prospecting in the district east of the Idaho-Montana line, where he owns a two-third interest in the Monide property, says that his adit is now in 300 ft. on the vein, which has a width of 12 ft. averaging 8% copper. Some of the samples run 5 oz. silver and \$16 in gold. A shipment of 1000 lb. sent to the Panhandle smelter for testing returned \$23, of which \$8.35 was deducted for excess silica.

SILVER BOW COUNTY.

A large number of men have been laid off by the Amalgamated Copper Co. at the different mines, especially at the Anaconda, Boston & Montana, and Butte Coalition mines.

NEVADA.**ESMERALDA COUNTY.**

The American Mining Congress is arranging to present forcibly to the Federal Congress at its next session to be held in Goldfield the demands of Western mining men for the amendment of the old and the passage of new statutes regulating mining. This will be done by eliminating as far as possible the undesirable features of the present United States, Mexican, and British Columbian laws, and incorporating all that is good into a new code. The law of the

apex will again be brought into prominence; for both Michigan and Arizona have so conspicuously shown freedom from litigation due to not using that law.

HUMBOLDT COUNTY.

(Special Correspondence).—The first carload of machinery for the mill being constructed for a London syndicate has arrived here, and, according to the manager, C. S. Floyd, will enable construction to be completed in about six weeks. The miners of the district are much encouraged, for connected with the mill will be a sampler where ore will be purchased both in small and large lots, enabling local operators to get quick cash returns. Samuel Harris, representing the London syndicate, intends the mill to be one of the finest in the State. All tank foundations and walls are of concrete, and heavy framed structures are being used for upper parts of the buildings. Ore will be treated by amalgamation, crushing to slime, and cyaniding, without any concentration; and as all grades of ore are to be treated, nothing will be shipped except bullion. D. H. Skae, the mill manager, has supplied further details about the plant: the ore will be weighed both before and after being discharged into the 10-compartment bins, which have a capacity of 300 tons. After the second weighing it will be elevated to the top of the Vezin sampler, which will take out 20%. The remainder falls onto a belt elevator which conveys it to the mill-bins, while the original sample is further crushed by rolls, and a tenth part taken out by a No. 1 Vezin as a final sample. The stamp battery consists of ten 1000-lb. stamps in which there is no intention to crush fine. Lip plates are attached to the mortars, and after passing over the amalgamating plates the pulp will be separated into sand and slime by a Dorr classifier. The sand is then to be fed by spiral conveyor to a 16-ft. tube-mill lined with an improved type of El Oro liner; the ground product will be elevated by a Frenier pump to a second compartment of the Dorr, whence all slime will flow direct to the cyanide plant. In the cyanide plant a 25-ft. cone classifier will serve as a de-waterer, the thick pulp being pumped by a Butters centrifugal to the agitators, while the overflow will be returned to the mill-feed. Before introduction into the four Brown agitators, cyanide will have been added, and agitation by compressed air will ensue for about 24 hours. Separation of the gold-bearing solution is to be effected by an Oliver continuous vacuum-filter; and the final stage of precipitation will be accomplished by 16 zinc-boxes. All accessories of the plant are on the same generous scale, and nothing is being left undone to ensure complete success for this new venture of the Seven Troughs district.

Mazuma, February 15.

LINCOLN COUNTY.

On July 1 the bill passed by the Senate for the division of Lincoln county will go into effect. Thereafter Lincoln county will extend as far south as the third standard parallel, all south of which will go by the name of Clark county, with Las Vegas as capital. Lincoln will pay \$10,000 to the new county as a proper share for property held by both at Pioche.

NYE COUNTY.

Fresno mining district is the name just given to the country around George's canyon, 40 miles northeast of Tonopah. The new camp is the scene of a rich strike lately made on the property of Stimler & Marsh. H. J. Wildegrube says that the mineralized section of the district extends over a large zone and when several of the properties are opened up the place may prove a valuable asset to Nye county. During the past week the MacNamara mine in Tonopah shipped 200 tons of ore to the Montana mill for treatment. The shipment was less than that of the previous week owing to work at the bottom of the shaft preparatory to sinking, which has been started. The shaft had to be timbered near the bottom, and now that this has been completed the work of sinking will be continued a farther 300 ft. to prospect some veins formerly cut by the diamond drill.—Edgar A. Collins is working on a system

for treating the concentrate of the Montana-Tonopah mill instead of shipping them at heavy freight and treatment cost. The Hutchinson process, used so successfully on the ores of the Goldfield Consolidated, will not economically treat the Montana ores, but it is possible that a modification may be introduced to suit the Montana conditions.—The MacNamara Mining Co. declares its intention of disbursing \$10,000 in dividends on the first of each month, beginning on March 1. There is also talk of constructing a mill, as the company's contract with the Montana expires in the middle of March.

STOREY COUNTY.

The first dividend to miners from the proceeds of the ore taken from the Ophir and Consolidated Virginia for the past three months has just been distributed. It amounts in all to \$1956, and has been distributed according to the wage earning capacity of the different men employed. The idea of the management is that when men are working on shares and know that they are to get a part of whatever the mine produces they will be more diligent in their daily duties and use every endeavor to do the best for the mine.—The Comstock Goldfield Leasing Co. is operating at a place about a mile east of Virginia City, and has mined silver ore of notable value, which is being shipped to Selby's at San Francisco by the superintendent, Joseph T. McCarthy. Previously it had been sending the output to the Butters plant in Six-Mile canyon, till the value of the shipments justified sending the ore down to the city.

WHITE PINE COUNTY.

A high-class fire-clay deposit has been found on the Haberson ranch, and a contract has been signed with the Steptoe Valley smelter to supply 100 tons per month, as it is fully equal in quality to that brought in from Ogden.

OREGON.

UNION COUNTY.

Ten stamps will be installed at the Humboldt mine in Mormon Basin, owned by the Humboldt Gold Mining Co. The shaft is down 200 ft., at which point a second station will be cut and drifts will be run.—W. L. Vinson is completing a deal by which he will dispose of his interest in the Intermountain group, better known as the Wagner property, in the Mormon Basin district, 35 miles east of Baker City. It is understood that Vinson's controlling interest will be sold to C. E. Bond, Andrew Hawkins, and J. W. Howser, who are all from Kentucky. They appear to be pleased with the property.

UTAH.

SALT LAKE COUNTY.

Dr. A. Penck, professor of geology at the University of Berlin, in a lecture to the mining students at the University of Utah, congratulated them on being trained in a region so rich in geological features. For not only does the Utah Basin contain ancient shore-lines, glacier deposits, faults, alluvial fans, etc., but the neighboring hills offer the students a varied field in the study of ore deposits and practical mining.

WASHINGTON.

FERRY COUNTY.

Work has been resumed on the San Poil mine in the Republic district, north of Spokane, after a shut-down of more than a year. George James has taken a year's lease on the property, which is the best known in that camp. It is opened by an adit to the 300-ft. level and has over 700 ft. of drift. A raise has also been made from the 300-ft. to the 200-ft. level. The average value of the ore is placed at \$15 per ton, and is three feet wide.

CANADA.

BRITISH COLUMBIA.

Official announcement is made by C. H. Dickie, of Victoria, that the Portland Mining Co., of which he is president, will install a smelter and an aerial tramway on its property, upon which more than \$50,000 has already been spent in development work. The company is a reorganization of the Portland Canal Mining & Development Co. and

is capitalized for \$1,000,000 in four million shares of 25c. each. The property consists of 12 claims at the head of Portland Canal, formerly known as the Missouri Stewart, and shows a well-defined silver-lead vein on six of the claims. W. J. Elmendorf, a mining engineer of Spokane, who examined the property, states that there are more than 20,000 tons of ore available.—The plant of the Canada Zinc Co. at Nelson has been five years in arriving at its present stage and represents an outlay of nearly \$125,000, of which the Provincial Government advanced \$20,000. The smelter has a capacity of 10 tons per day at present, but now that it has passed the experimental stage the capacity will be increased to 30 tons per day. The ore so far treated has averaged 40% zinc, 10% lead, 12 oz. silver, and 1 to 5% copper per ton. A vertical furnace, heated internally by electricity is used at this smelter. The electrical heating does away with the horizontal retorts commonly used in zinc smelting, and much labor and breakage is also saved. At the other smelters of the district, zinc has been penalized, as the zinc oxide residues tended to block the flues. Now that both lead and zinc can be treated together there will be quite a stimulus to production in the Nelson and Kaslo districts.—Great interest is being taken in the recent discoveries of copper-bearing ores in the vicinity of Vancouver.—The West Canadian Placer Co. has been formed with a capital of \$75,000 to acquire an option on the Turner mining lease in the Cariboo.—A big deal in mining property has nearly been accomplished in northern British Columbia. The vendors are a syndicate composed of William Noble, W. H. Collison, John Flewin, and a company known as the Alaska Smelting & Mining Co., the first three named being the vendors of the larger part of the property. The purchasers are the Associate Mining Co. of London. The deal has been brought about for the company by Cecil M. Bryant. The properties comprise about 40 claims situated on the east side of the Portland canal, 70 miles north of Port Simpson, at a place designated on the map as Maple bay. Considerable development has already been done at the mines, and 12,000 tons of ore have been shipped up to date.—A reorganization committee for the Dominion Copper Co. has been formed by the leading bondholders and stockholders, comprising Charles Hayden, of Hayden, Stone & Co., chairman, W. W. Foster, John A. Sleicher, Warren Curtis, Channing Stebbins, James Williamson, and Henry H. Melville. The Dominion Copper Co., now in the hands of the court, has outstanding \$800,000 of bonds, with \$28,000 of unpaid interest thereon, \$100,000 of floating debt, and 50,000 shares of stock, par \$10. The reorganized New Dominion Copper Co. will issue \$500,000 of 6% ten-year income bonds, 250,000 shares of common stock of a par value of \$5 per share. It is announced that should a large amount of additional capital be necessary to develop the properties and construct smelters, etc., it may be found advisable to sell the property rather than take the chance of continuing at a loss.

ONTARIO.

The constant improvement in the position of the silver market will prove an important factor in the dividend returns of the Cobalt mines during 1909. The advance in the price has been about five cents an ounce from the low level of last summer, when China was a heavy seller of silver. The advance of five cents an ounce means an increase in the value of the Cobalt output of nearly \$1,000,000, taking last year's production of about 19,000,000 oz. as a basis. This would be over 2% on the entire capitalization of the dividend-paying mines. Many silver experts expect that a price of 60c. an ounce is among the probabilities of the year.—Cobalt Central has made some rich silver discoveries at a depth of 400 ft. under Diabase Mtn.; and is at a greater depth than any other mine in the region except the Jacobs on Kerr lake.—During January the Nipissing Co. mined ore of an estimated value of \$128,000. Important development work was done on the 130 ft. level of the Fourth of July shaft, as a 1 in. vein has been followed across a fault and found to be 6 to 8 in. wide, carrying on an average 3,000 oz. silver per ton.

Special Correspondence.

LONDON.

Radium Minerals.—Venture Corporation.—Broken Hill. — Engineers Club.—South American Mining.—Associated Northern Blocks.

It has long been felt by the leading members of the Institution of Mining & Metallurgy that mining men are in want of greater facilities for social intercourse than their Institution can, from its nature, afford them. The founding of an engineers' club has always seemed a desirable innovation, and the time is now ripe for doing something of this sort. As a means of sounding the profession as to the requirements and possibilities, a number of leading men have called a meeting for January 28, to be held at the Waldorf hotel in the Strand, and have invited members of the Institution to attend. The proposal is that a meeting of this sort be held once a month, when members can discuss matters of general interest and the papers read at the preceding meeting of the Institution. The meeting will not be formal. No reporters will be present, so that men will feel free to exchange views. The meetings of the Institution are held at the rooms of the Geological Society, and at the entrance is a notice prohibiting smoking on the premises, a fact which gives many men the impression that the meetings are solemn and unsympathetic. At the proposed club assembly smoking will be allowed.

Radium mining is a small industry at present and it is not safe to prophesy its future; nevertheless, everybody who knows anything about pitchblende is turning over his dump and examining his stopes. The inclination to do this has received a fillip lately by the announcement that a Radium Institute is to be founded in London. The English medical men have become convinced that certain of the emanations of radium and its compounds are efficacious in treating skin and other diseases and they have received the financial support of Sir Ernest Cassel and Lord Iveagh, two millionaires who are continually giving liberally toward medical research and other objects for the improvement of social conditions. At the present time there is a radium institute in Paris where research and hospital work are carried on, and in Vienna a laboratory for research work only is being erected. At the London institute both paying and poor patients will be treated, and research work carried on. As regards the source of radium, efforts are being made to utilize the pitchblende that exists in Cornwall. For many years the sole commercial output of this mineral came from the Uranium mine, which is situated between Truro and St. Austell. In 1907 the output was 71 tons and probably the figure for 1908 will be similar. Some of it is treated in London and some in the pottery district of Staffordshire, but the bulk goes to Germany. The uranium products obtained from it are used for coloring glass and pottery enamels, and in photographic work. A year or two ago the owners of the mine tried to raise money to treat the ore on the spot and to extract radium from the residues, but this scheme fell through. At the present time another mine, the Trenwith, near St. Ives, is being opened up for pitchblende. The mine belongs to the St. Ives Consolidated, a company formed by the Messrs. Schiff some months ago to acquire a number of old tin mines in the neighborhood. In the stopes and on the dumps are found quantities of pitchblende, which in the old days was left untouched or sorted out. A subsidiary company, called the British Radium Corporation, has been formed to deal with the pitchblende and produce radium from it. Sir William Ramsay has examined the mineral and has reported favorably on its radio-activity. Pitchblende is found in a great many other mines in Cornwall, but not in commercial quantity.

I recorded some weeks ago that the Venture Corporation had been successfully reconstructed under the name of the London Venture Corporation and that the outlook for its future seemed promising. The statutory meeting of share-

holders in the new company was held this week, when it was announced that the subscriptions had come in well. Besides the 300,000 fully paid 4s. shares, approximately 400,000 had been allotted with 2s. credited as paid. In addition, 2007 shares had been subscribed at par (4s.); so that altogether the new company starts with a cash capital of £40,400. The chairman, F. W. Baker, took the opportunity of sketching an outline of the company's projects and policy. One item of news is that negotiations are pending whereby additional capital will be subscribed in America by parties whose names are not yet divulged, and that the company is to have offices in New York and Chicago, where its interests will be looked after by local representatives. A property in New Mexico, where a 40-stamp mill is being erected, is to be examined with a view to purchase, also a gold gravel property on the Atrato river in Colombia. Oil-lands in a French colony, mineral lands in a State of Central America, and a mineral estate in South Africa were also mentioned. Perhaps this information may be supposed to be too vague for recording here, but at a statutory meeting of a company like this it is not usually considered good policy to give details of deals that have not yet been consummated.

Six months ago, when referring to the effect of the slump in metals on the Broken Hill silver-lead district, I mentioned that Block 14 Company had found it necessary to shut-down their sulphide mill entirely, as their ores are not quite so rich as those found on some of the neighboring properties. The mill is still idle, but other work is not in abeyance. Development of the orebodies continues and considerable quantities of the carbonate ore in the upper levels is still being mined and sold to the Broken Hill Proprietary. For instance, during the six months ended September 30 last, 15,525 tons of carbonate ore was disposed of in this way, as compared with 13,762 tons during the half-year before. The average content of this ore was 33% lead and 12 oz. silver, representing 5159 tons of lead and 189,342 oz. silver. The price obtained was £40,639. This part of the mine continues to open up well and there is about six months' supplies ready for stoping. As regards the sulphide ores, it is estimated that above the 600-ft. level the reserves amount to 220,000 tons averaging 12% lead, 8½ oz. silver, and 9% zinc. The expenditure on mining, development, maintenance, and provision for depreciation comes to about £38,000. The balance in hand now amounts to £85,000, and the company is only waiting for a rise in metals to go ahead successfully.

In my last letter I referred to the proposal to start some sort of a club for mining engineers in London. The inaugural or experimental meeting was held on January 28 and proved a great success. There was a large attendance in spite of one of London's densest fogs, and the proceedings were thoroughly enjoyed. It was decided to go ahead and the committee was asked to formulate further proposals. A good deal of time was occupied by an informal discussion on H. W. Hixon's paper on the genesis of ore deposits, read at the January meeting of the Institution of Mining & Metallurgy. Speeches were limited to ten minutes and they were both lively and pointed, a great many of those present participating. As regards the future meetings of the club, it is felt that it will hardly be good policy to discuss papers read at the Institution's meetings, because it would tend to lessen the interest of the regular meetings. The readiness of members to talk at the club meeting as compared with their diffidence at the Institution's meeting indicates that many would purposely postpone their remarks. This would not be fair or good policy.

On previous occasions I have referred to the inclination of promoters and mining men to introduce South American propositions to the investing public. An interesting example is to be found in the Rio Del Oro Co. Ltd., which has just been floated to acquire dredging and gravel concessions in the river Yuruary in Venezuela. The promoter is H. E. M. Bourke and with him are associated as vendors Gerald Browne, of the firm of Pearse, Kingston, & Browne, mining engineers, and N. G. Hackney, also a mining engi-

neer. All these gentlemen are intimately acquainted with the property, and their views and opinions are endorsed by Frank Merricks, of the firm of Merricks, Crane & Co., who made an independent examination. The river Yuruary has long been known for its auriferous gravels, and the concession acquired by this company is additionally interesting owing to its being situated just below the famous El Callao mine. This mine has in its time produced great quantities of gold, and the whole of the tailing from the batteries was discharged into the river. Records show that 1,500,000 oz. were extracted from 700,000 tons of quartz, and that the tailing averaged 9 dwt. per ton. No attempt was ever made to recover the pyrite from this tailing or in any other way to extract the gold contained in them. To re-treat the accumulation of tailing is one of the objects of the Rio Del Oro Co. The vendors and Mr. Merricks give very full information relating to the banks of gold-bearing gravel, and altogether the enterprise is attractive.

A year ago Hermann Landau, chairman of Associated

30 last, £87,500 was distributed in dividends. Altogether, gold to the value of £1,397,812 has been recovered from 226,681 tons of ore since the mine commenced operations.

NOGALES, ARIZONA.

Sale of Pilares.—Geology of Santa Cruz District.

The rumored sale of the Pilares mine in the Santa Cruz copper district of northern Sonora, to Greene-Cananea interests, through W. C. Greene as agent, marks the commercial result of a development enterprise which began about December 1906. At that time Eduardo Arnold, mayor of Cananea, a Mexican citizen of Swiss descent, began to develop a copper prospect in the foot-hills of the southwestern slope of the Santa Cruz mountains, a low range forming the geographic and geologic continuation of the Patagonia mountains of Arizona. The presence of copper at the point where development was begun was suggested by slight green stains of malachite or diopside on the surface outcrops of the country rock, and some earlier prospector, in sinking two shallow holes, had encountered some small stringers of chalcopryite. Mr. Arnold, with the spirit of adventure so necessary in developing prospects, sank a shaft near the old prospect-holes, and, soon encountering a substantial mineralization of chalcopryite, drove a tunnel to meet the shaft from the bank of an arroyo about 100 ft. below. He has since continued the development to a depth of 400 ft. with satisfactory commercial results.

A brief reconnaissance of the geology indicates that the country rock is largely quartzite, intruded by a coarse grained eruptive, probably mica-diorite, and cut by dikes of quartz-porphry and andesite. A substantial dike of the latter is near the orebody and may have been the exciting cause of the mineralization. The copper ore is chalcopryite, with small amounts of secondary bornite and occurs either in the quartzite, filling interstices and crevices, or in a quartzose gangue which has some characteristics of the filling of a fissure vein, but is more probably a segregation.

The orebody has widths ranging from 15 to 30 ft., has been opened for some distance along the vein, and is said to average considerably over 8% copper. A striking feature is the very slight surface indication of the presence of this deposit, but it is also true of the larger orebodies at Cananea that they did not underlie the strongest gossans and were chiefly found by blind driving. Obviously, gossans come from the decomposition of metalliferous deposits, and if the surface erosion has not reached their upper limits, no gossans can be exposed.

On account of this mine being within 50 miles of Cananea and within three miles of the railway recently constructed between that city and Nogales, the ore will be of great value to the Greene-Cananea company as a source of silica. At the time when substantial bodies of chalcopryite were first found in the Pilares, some excitement arose in the neighborhood and many denunciations were made on the ground surrounding that of Arnold. Colonel W. C. Greene took up 4000 pertenencias, but this area was subsequently greatly reduced and his claims are now being prospected by the Greene-Cananea people. Little development work has been done on the other claims in the vicinity, chiefly for lack of funds; as yet, outside of the Pilares mine, little is known as to the possibilities of the locality, although chalcopryite has been found on neighboring properties. The chalcopryite is probably a secondary enrichment and, so far as one may judge from available information, no one may now venture an opinion as to whether this zone of enrichment extends to great depths, or whether it will soon give place to a leaner primary ore. At many points in northern Sonora, the primary copper ore is found to be iron pyrite carrying 2 to 3% copper. In semi-arid countries the fluctuation in ground water-level is excessive, sometimes having a range as great as 100 ft., and this occasions great irregularities in the resultant decomposition of secondary enrichment.

Map of Arizona.

Northern Blocks, one of the mines at Kalgoorlie, lamented that the mine showed signs of exhaustion and that the company was unable to carry out extensive exploration in depth. Indeed, it was on this occasion that he startled the world by suggesting that deep exploration should be undertaken by the Government out of the public funds. At adjoining mines, such as the Great Boulder Proprietary and Lake View Consols, good ore has been struck at lower levels than was generally expected, and it was hoped that Northern Blocks would do likewise. However, no such work has been deemed advisable by George Roberts, the manager. Further disappointment ensued in opening up the ore reserves. In several parts of the mine the grade has been found to be much lower than was anticipated, and the recovery has fallen considerably. A year ago it was estimated that the reserves would last three years and would yield 12 dwt. per ton. At the present time Mr. Roberts is having to work 8-dwt. ore, and does not feel sure that the reserves will last for much more than a year. The directors are now casting about for a new property. They tried the Southern Cross without success, and are now developing Harbour Lights, though they are not hopeful about it. Arrangements are now being made to extend the field of operations outside Western Australia. The company is in a strong financial position, for it has a reserve fund of £130,000 invested in Government securities. During the year ended September

CHICAGO.

Oil Production.—United Mine Workers. — State Geologists. — Electrical and Automobile Shows.

Oil production in Illinois continues to increase. Early this month the Ohio Oil Co. announced it would take 80%, instead of 60% of the output. This, with the 5800 bbl. that the independents handle, makes practically 100,000 bbl. per day now being run. Even at this rate it will take some weeks to relieve the congestion and run off the accumulated stock in producers' tanks. Several months will elapse before the Tidewater line from Rixford, Pa., to Robinson, Ill., is completed. Approximately 300 miles remain to be constructed. Both the pipe and telegraph lines have been finished from the east into Ohio and at the west end from Robinson into Owen county, Indiana. Five gangs of men are being used and the work is going forward steadily despite winter weather. The line is expected to be ready to take oil this spring. While local producers have got along well with the Standard and there has been an entire absence of the friction that has characterized the development of so many oilfields, an independent outlet will be welcome because of the increased production possible. Small oil-wells continue to be brought in at various points in the western part of the State, but the field is still uncertain. The *Oil Field News* has been established at St. Louis to cover this territory.

The United Mine Workers had a lively session at Indianapolis, but apparently the different factions have agreed on a working program and intend to present a united front. The re-election of Tom Lewis as president was at first sharply contested by J. H. Walker, who led in severe and bitter attacks on the administration. Eventually, however, he withdrew from the contest. No candidates having received majority votes for vice-president and secretary-treasurer, the election was thrown into the convention, with the resulting selection of E. S. McCullough for the first-named office and Edwin Perry for the second. Mr. McCullough was born 41 years ago in Ohio. Like many of the miners' leaders, he is self-educated and is a socialist. He has been president of the Michigan miners. Mr. Perry is a Welshman, having been born in north Wales 54 years ago. He, however, came to the United States in 1869 and has worked both in the anthracite and bituminous fields. He comes to his new office from Iowa. Messrs. Lewis, McCullough, and Perry will be the official heads of the largest labor union in the country and a most powerful factor in one of our basal industries. Whether they will at the same time become real leaders, it is too early to say. Many informed observers doubt the ability of Lewis, in particular, permanently to hold the organization together, and it was demonstrated at Indianapolis time and again that John Mitchell is still the most popular leader in the organization.

Interest in coking of Middle West coals continues to increase. It is announced that the H. C. Frick Co. is to build a bank of by-product ovens in the Chicago district in place of enlargements at first contemplated at Connellsville. A number of other concerns are quietly looking into the situation and it will probably not be long before a beginning is made.

It is announced that L. P. Breckenridge, professor of Mechanical Engineering, and director of the Engineering Experiment Station at the University of Illinois, will go at the end of the year to a similar position at his alma mater, Yale. Professor Breckenridge has been an active factor in the development of better uses of Illinois coal and his going will be a distinct loss to the State. In Indiana a bill has been introduced in the House to abolish the office of State Geologist, but it is not likely to pass. Despite the peculiar organization of the department in Indiana, it being frankly political, the present State Geologist, Mr. Blatchley, has done good work.

The annual succession of shows at the Coliseum is now on. Last week it was the electric show, now the automo-

bile, and soon the cement products exhibition is to follow. It is hard to estimate the importance of these annual exhibitions, but they seem to have become a fixture and undoubtedly have a broad educational influence. Necessarily, they are arranged to interest the average householder and citizen, but there are always a few things of especial import to mining men. At the electrical show, aside from mine telephones, cables, lamps, and motors, there was an exhibit by the Northern Electric Mfg. Co. of a new electric rock-drill. The drill is of the high-speed hammer type, the blow being given by a rotating helve carrying two hammers, cushioning on air. The mechanism is ingenious and offers distinct possibilities. The type shown impresses one as too bulky and heavy for most underground work, but it ought to be possible to re-design the machine to meet special conditions. In its present form it is better adapted to quarry work. It has been tried in the zinc mines of Wisconsin with some success. The automobile show contains much of interest to mining men, though in general the types shown are adapted more to city and suburban use. The Illinois Society of Engineers and Surveyors held a successful meeting at the Great Northern the last of the month.

TORONTO, CANADA.

Railroad to Gowganda. — Developments at Cobalt. — Government Royalties.—Conviction of Mine Promoter.

The new silver camp at Gowganda is now accessible by rail, a daily service having been established with Toronto. The sleigh and wagon-road from Sellwood, the end of the line north of Sudbury, having been completed, the first train from Gowganda left this city on February 2 over the Canadian Northern railway. On reaching Sellwood by way of Sudbury freight and passengers are forwarded to their destination by the conveyances of the Gowganda Transport Co. A party left this week for a trip of inspection, among them being J. B. Tyrrell, J. C. Murray, and J. W. Bartlett. Arthur Hawkes, the publicity agent of the Canadian Northern, has extensive projects in view in connection with the development of the region. At Gowganda great activity in building prevails, and freight and materials are being rushed in. Discoveries are daily reported, and claims are changing hands at high figures. It is impossible to verify these statements, many of which are doubtless exaggerated, but there is no question as to the rapid development of the camp.

The depression in mining stocks continues, notwithstanding the heavy shipments, and the respectable dividends paid by the leading Cobalt mines. The market has been flat since the middle of December. The most noticeable feature during the last few days has been the break in Silver Queen. The shares which had been fluctuating between 90 and 100 suddenly fell about 20 points. The only apparent reason was a rumor that the dividend might be passed, which was contradicted today by an official statement that the cash is now in hand for its payment. Other companies, chiefly of the non-dividend paying class, have also materially weakened. One cause of the depression is no doubt the Gowganda and Montreal River booms, and the numerous new flotations, either actual or prospective, which are absorbing the attention of investors to the detriment of the older issues.

At the Nipissing Fourth of July shaft at 135 ft., three new veins, two 1 in. wide and one 4 in., yielding 4000 oz. per ton, were recently found. At the Silver Bar the original shaft has been abandoned and two new ones started, in both of which good ore has been developed. One of them is down 90 ft.; the other has reached a depth of 30 ft. on a 3-in. vein showing native silver. Latest developments at the Crown Reserve indicate that its position as a prominent shipper is likely to be maintained. No. 1 shaft, which is 100 ft. deep, and No. 2, now down 145 ft., are both to be sunk to the 200-ft. level. They were recently connected by a drift, in both floor and roof of which the vein is 16 in. wide, and very rich. In addition to drifting on the main vein, a cross-cut has been driven some 200 ft., and a num-

ber of smaller veins showing good silver content have been revealed. Development has been temporarily suspended at the Colonial mine for the erection of a stamp-mill and concentrator, the mine having large deposits of low-grade ore. The smelter of the Montreal Smelting & Refining Co., at Trout lake near North bay, is now in active operation and has received large consignments of ore from the Temiskaming and McKinley-Darragh mines. The La Rose is shipping high-grade ore taken from the raise at the 200-ft. level. The vein is 11 in. wide, containing cobalt and silver with a little calcite, and the wall-rock is heavily impregnated with native silver. The value of the high-grade ore reserves at the Temiskaming & Hudson Bay is estimated at \$1,500,000. The main shaft is to be sunk from 200 ft., the present depth, to 250 ft. The O'Brien mine has paid \$49,518 to the Ontario Government, being 25% royalty on the output for the last three months of 1908.

The annual meeting of the shareholders of the Dr. Reddick mine, one of the most hopeful of the Larder Lake enterprises, was held at Ottawa February 1. It was decided

State of Jalisco, Mexico.

to increase the capital to \$2,500,000 by the issue of \$500,000 in 8% cumulative preference stock. The superintendent's report showed that the first 30 tons milled yielded \$8 worth of gold per ton, and the next 100 tons between \$10 and \$12 per ton.

Frank Law, a mining promoter and broker, accused of conspiracy to defraud in connection with the Highland Mary, Blue Bell, Lucky Boys, and other flotations, was brought to trial here last week and found guilty. The evidence showed that Law and his confederates had received subscriptions amounting in all to about \$250,000 for the shares of these worthless concerns. Law's defence was that he had been promised immunity for information in the extradition proceedings against W. Lockhart Russell, alleged to be the leading spirit in the fraud. Sentence has been deferred, Law having taken an appeal on the ground of his having been used to assist in the proceedings against Russell. It is said that Russell has at last been discovered somewhere on the Pacific Coast, and that the extradition case would be proceeded with, but up to the present he has not been apprehended. Law appealed, but his appeal was denied, and he has been sentenced to five years imprisonment. He evidently still entertains hopes of escaping or of a mitigation of the severity of the sentence, as he is now going over the books and papers of his companies with the officials, for the purpose of saving something out of the assets, wherewith to make restitution.

GUADALAJARA, MEXICO.

Navidad Mines. — Amparo Dividend. — New Plant at Tenemache. — Lawson Development Company.

California men who are interested in the Navidad Mines & Reduction Co., operating in the San Sebastián district of Jalisco, are preparing to furnish electric power to mines and mills in that and adjacent districts. They have secured a concession to use the water of the Ameca river, and have planned a hydro-electric installation capable of producing 5000 hp. The power will be transmitted as far as the Compostela district of Tepic, where some of the men of the Navidad company are also interested. S. C. Irving, president of the Paraffine Paint Co., of San Francisco, is president of the company, and R. S. Penniman, manager of the Pacific Coast department of the Du Pont Powder Co., and H. H. Tracy, of the Tracy Engineering Co., of San Francisco, are among those heavily interested. The California men bought the mines from a Mexican company about two years ago, the contract price being \$300,000. They will soon replace the existing reduction works with a modern plant, and will give the mines connection with the Pacific port of Las Peñas by the construction of a wagon-road. Messrs. Irving, Penniman, and Tracy recently visited the Navidad properties. The Amparo Mining Co., of Philadelphia, operating in the Etzatlán district of Jalisco, is again on a dividend-paying basis, the directors having declared one of 2½%. It is announced that this will be paid quarterly, making an annual dividend of 10%. The quarterly dividend amounts to \$63,000, and the capital stock on which it is paid is \$2,520,000. Two years ago the company paid a dividend of 3%. The affairs of the Amparo company, which for nearly a year have been in charge of James H. Howard as general manager, are in excellent shape, and it is believed that from now on dividends will be paid regularly. The production amounts to about \$30,000 per week.

The Tenemache Mining Co. of Guadalajara has just placed an order for reduction machinery for the Tenemache mines at Zopilote, Tepic. The order covers 10 stamps, re-grinding machinery, concentrators, cyaniding equipment, boilers and engine, and electrical equipment. The machinery will be delivered at the Pacific port of San Blas in time for its transportation to the mines before the opening of the next rainy season. The mines, which are *antiguas*, have been under development by the present American company for nearly two years, and a large tonnage of milling ore has been blocked out.

Thomas Kelly, president of the National Livestock Commission Co. of Chicago, F. H. Morley, of Denver, and John A. Kruse, of Chicago, have just completed an inspection of the Ojo Verde copper property in the Autlán district of Jalisco. They were accompanied on the trip by S. F. Ossolinski, who secured the Ojo Verde for Mr. Kelly last year. Plans for extensive development are being formed. The Ojo Verde is an immense virgin deposit, and the property has been 'denounced' for a distance of nearly a mile.

Frank W. Page, general manager for the Lawson Development Co., states that arrangements are being made to carry out the plans made by the company early last year. The custom reduction plant of the San Gerónimo hacienda in the Mascota district of Jalisco will be completed, Mr. Page says, and work will be resumed at several of the company's properties. The purchase of mines on which options were secured last year will be taken up a little later. Mr. Page recently returned from Boston, after a conference with Thomas W. Lawson. Ore assaying 212 gm. gold and 300 gm. silver per ton has been found in the mines of the Quien Sabe Mining Co. at Ajijic, Jalisco, on the northern shore of Lake Chapala. The rich ore will be sacked for shipment. Development has been in progress in the Quien Sabe mines for several years, and a modern reduction plant has been erected. Patrick E. Blalack, of San Antonio, Texas, and C. H. Maris, of Brownsville, Texas, are the principal shareholders in the company.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Ice, on melting, yields five times as much water as an equal bulk of snow.

Platinum vessels are attacked to an appreciable extent by fusing borax in them. It has been determined that 200 gm. of borax fused in a platinum dish will take up as much as 0.46 milligram of platinum.

Borax and fluorspar should not be used together in fluxing gold and silver precipitates. The two are mutually destructive, and give rise to bubbling from the evolution of boron fluoride, and that in turn causes loss from 'dusting'.

Uranium may readily be extracted from pitchblende by calcining the pulverized mineral with sodium carbonate, and leaching the fused mass with hot water, and then, with sulphuric acid. The uranium will pass into solution and may be precipitated as hydroxide by ammonia.

Stream piracy is a name given to the phenomenon occurring through the erosion of one stream across the water-parting into the drainage basin of another stream, diverting the latter into the new channel. Valleys are often left thus robbed of their original streams, and what were formerly water-gaps through mountain ranges are converted into wind-gaps.

Ferrosilicon slowly decomposes, the carbon, phosphorus, and arsenic present yielding arseniuretted hydrogen, phosphoretted hydrogen, acetylene, hydrogen disulphide, and hydrogen. It is said that one ton of ferrosilicon will spontaneously give off about 12 cu. ft. of such gases in 24 hours. On this account it renders the atmosphere dangerous when stored in close quarters.

Tube-mills will crush dry or wet. For cyanidation there are reasons why dry crushing would give superior results. Rolls also are efficient dry crushers if the attempt be not made to reduce the material too far. The average maximum size of the ore fed should not be reduced finer than one-third that diameter. Rolls cease to be economical crushers below about 2 mm. diameter.

Self-shooter is the name for an automatic device for clearing sluices of the accumulated boulders and debris. Water is allowed to accumulate behind a small dam. When this is full, some water flows down a pipe into a barrel suspended at one end of a lever, the other end of which is connected with the gate. When the barrel is filled, the gate is raised automatically, and releases the accumulated volume down the race and flume, effectively clearing away all boulders and tailing.

Dynamite rapidly deteriorates in water by solution of the sodium nitrate employed in the 'dope'. The 'dope' of ordinary dynamite consists of wood-pulp,

to which enough sodium nitrate is added to supply oxygen for its combustion. As soon as the nitre has been dissolved the 'dope' ceases to hold the nitroglycerine as a uniform mixture, the nitroglycerine leaks out, a miss-fire is liable to occur, and free nitroglycerine will be left behind, which is many times more sensitive to explosion by shock than dynamite.

Sizing tests are not referable to any standard sizes of screens in America, hence a screen-analysis has no significance unless the diameter of opening and of wire are both stated, together with the method of screening, whether wet or dry, and the kind and number of shakes given. Standardization of screen analysis has been introduced into cement-testing, and a very unscientific order of mesh-sizes has been adopted as standard by the Institution of Mining and Metallurgy.

Peat is being used to a larger extent each year in Europe, owing to the growing cost of coal. In America it has not met with favor, owing to the many inconveniences attendant upon its use. For domestic purposes it is objectionable on account of the large quantity of ash produced, and the necessity for maintaining a brisk fire. It will not make a 'banked fire' like coal. For boiler firing, using automatic stokers, and water-flushing of the ashes, it is a satisfactory fuel.

Cement clinker is unaffected by moisture, and clinker that has been stored for some time produces superior cement to that fresh from the kiln. It is not improbable that it will become customary to establish grinding mills in important centres of consumption for cement, so that clinker may be purchased and ground on contract as required. This will effect great economy, and will insure freedom from adulteration and the working off of poor cement as largely practised today.

Cyanimide is a compound having the formula CaCN_2 , formed by passing nitrogen over calcium carbide at a high temperature. This substance, by melting with appropriate fluxes, produces potassium or sodium cyanide; acted on by steam it yields ammonia; and it is used directly as an efficient aid in the tempering of steel. Its chief use is as a fertilizer, as which it is equal to Chile saltpetre. It can be cheaply produced wherever water-power is available at moderate cost. Cyanimide works of large capacity are being erected in all parts of the world.

Desilverizing of lead bullion is usually done by the addition of zinc to the molten lead. Granulated zinc is placed in a basket of iron wire-cloth, and immersed in the kettle of lead; the bath is then stirred, and the zinc alloying with silver more readily than lead, and being of lower specific gravity, rises to the surface as a scum or 'crust', carrying the silver with it. The 'crusts' are skimmed off and 'liquated' by heating in a form of reverberatory furnace with an inclined hearth, the lead being thus drained from the zinc. The crusts are then distilled in a graphite retort, to drive off the zinc, leaving a base silver residue, which is melted and refined.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

A Valued Subscriber.

The Editor:

Sir—Enclosed please find the sum of three dollars in gold dust for which you will place to my account and renew my subscription when due. I send now, as it takes a long time for a letter to reach San Francisco from here, and I wish to be on time so as to keep the MINING PRESS coming right along.

LEWIS LLOYD.

Shungnak, Alaska, September 10.

[The 'dust' consisted of a number of small flat nuggets weighing about 3 dwt.; the latter had been four months on the way, but it was welcome as evincing the usefulness of the PRESS to those who live on the outposts of empire.—EDITOR.]

Protection of Investors.

The Editor:

Sir—The reported discussion by the Mining & Metallurgical Society of America of provisions for the protection of investors in mining properties seems, to me, to have one serious deficiency, in that it deals chiefly with established mines having ore reserves, which can be measured or estimated.

This is the class of properties most interesting to the mining engineer, and if these were the only properties offered to investors the assumed task of the Society would be simple, but unfortunately this is not the case. For every established and paying mine whose stock is on the market there are at least 1000 that are trying to become established, and for every property with enough ore developed to justify the erection of a reduction plant on the smallest scale, there are probably 500 in which no commercial orebody has yet been found. All of these mining properties need money with which to operate, and their stock is on the market, not necessarily in the exchanges of the large cities, but is being offered to private individuals throughout the country. Further, no effort is spared to sell this stock, for the sales-agent receives a commission of from 25 to 50% of the money he secures for the company. Many and crafty are the ways in which these sales-agents operate. A fruitful method of raising money is by selling stock in small quantities among poor people. Women sell stock to factory girls, saleswomen in stores, to waitresses, chambermaids in hotels, and to other wage workers. Clever tongued men sell stock among farmers, and other residents of rural communities. Sometimes physicians and dentists are led to solicit subscriptions among their patients, and even retired clergymen from former members of their congregations. By exhaustive methods of securing information, trustees of estates are found in country towns, and if they are amenable to argument, are bribed to invest a part of their trust funds

in the stock of certain supposedly meritorious mining companies. Again, bank presidents or cashiers in country towns are sometimes approached, and by the donation of a block of stock are led to recommend the investment to some of their more affluent depositors. Of course such work as this must be handled by skilful men, and commands a good remuneration. Ethically the objection to these methods is that the agent is often wholly ignorant of the merits of the property or its proposed management and so, proves, in many cases, to have been guilty of obtaining money under false pretenses.

So much for the dangers which beset the investor in deciding upon a purchase of mining stock. He is not, usually, so fancy free as the lady who chose a certain mining stock as an investment because its color matched that of her hand-bag. His troubles, however, are not yet over with the consideration of the character of the property. The general question of administration is still before him, and is a fruitful source of danger. Without going into details of technical incompetency or of gross dishonesty on the part of employees, there remain to be considered matters of administrative economy, one of the most important of which is the mine store. As mines are usually at a distance from distributing centres for merchandise, it is generally necessary to establish at the mine a store to supply the employees with provisions, clothing, and other necessities. Without having accurate figures from different camps for comparison it may be said that in Mexico from 50 to 80% of the miner's wages is paid through the store, and in the United States from 25 to 40%. Bearing in mind the large profits taken by many company stores, ranging from 40 to 50% in the United States to 60 or 80% in Mexico, it may safely be stated that a mine-store frequently receives as profit from 20 to 40% of the monthly pay-roll, and occasionally as much as 50 to 60%. In the case of a company organized for the benefit of its stockholders, the mine-store should be a part of the mining enterprise, and its profits should be a rebate against the cost of operation, but everyone who has lived or traveled in mining countries knows that, in many instances, the store is a private perquisite of some favored officer, or officers, of the company, and that often, through years of development or other unproductive work, the mining business shows no profit, while the store returns every month to its owners a substantial percentage of the pay-roll. In a large camp the business of supplying meat is sometimes kept separate from the store, and this also may be a perquisite of some favored official. Every mining engineer of experience knows these things, but in many cases, in the position of superintendent, he has no voice in their disposition. He is simply paid to look after the technical end. Yet the technical end cannot wholly protect the investor.

The question therefore is, can the Mining & Metallurgical Society of America achieve protection for the investor? If not, let us be frank and admit our limitations, and if the blame for lack of protection should and can be placed elsewhere, let it be

placed where it belongs. The writer claims that the investor is generally at a disadvantage through lack of knowledge of the methods used in promotion and stock-selling; also through lack of knowledge of the general principles of mine administration.

As a strictly ethical proposition, no mine administration should be considered as wholly in the interest of the stockholders, where the profits of the mine-store are not an asset of the company. Of course, where the mine is paying dividends, the question is never raised, but with many a company, the mining business never makes a return to the stockholders, while the store pays good profits to its owners.

Electric Counter-Balanced Hoist.

The Editor:

Sir—Referring to C. W. Van Law's contribution in your issue of November 14, I would state that a notable instance of counter-balanced hoist of this kind was that installed in 1895 by Thomas H. Leggett at the Standard mine in Bodie. It was an ordinary 50-hp. Lidgerwood geared hoist, and while it had a capacity of about 400 ft., to equalize the load which was on the same circuit as several other motors, the drum was divided by boring holes through the cast-iron shell and bolting on a ring of wood capped with iron. The counter-balance was arranged as in Mr. Van Law's case, so that the motor was doing equal work when hoisting the counter-balance and hoisting ore. An interesting feature about this was that the travel in the counter-balance compartment was insufficient, the shaft being blocked in some way. Accordingly on the top of the counter-balance a running-sheave was fastened, set diagonally in the compartment, so that as large a sheave as possible could be used and avoid undue bending of the rope. The counter-balance rope passed down the shaft underneath the sheave and up again to an anchorage at the top. This device worked with entire satisfaction for many years, and, so far as I know, is still operating in that shaft.

Some years before this I arranged the installation of a similar over-balanced hoist at the Colusa Parrot mine at Butte. It had a first-motion engine, with Corliss valves. The counter-balance ran on special guides in the pump-compartment. It accomplished the desired end of equalizing the strain in consumption and economizing fuel admirably.

Diamond Manufacture.

The Editor:

Sir—The valuable and interesting article on 'Researches in Diamond Making,' by F. H. Mason, which appeared in your issue of December 5 last, is of special interest to me, and strangely coincides with the mechanical ideas I had in view for accomplishing the same purpose. My plans were to use tubes heated electrically, and to bring the pressure up to 50 to 100 tons per square inch by the superheated fluid and gases within. I thought of employ-

ing cannon-steel 5 to 10 in. thick, and nested several times. On their inner walls the tubes were to be lined with a hard carbon lining. They were to be anchored in a strong solid formation and to rest in the centre of a 5 to 10-ft. cube of reinforced concrete, everything being arranged to handle the work from a distance by electrical connections, and thus avoid personal injury. Mr. Threlfall's hydraulic appliance using graphite is simpler. I take issue, however, with Mr. Threlfall's chemical ideas in regard to the formation of the diamond. The attempt to crystallize it out of graphite at temperatures of from 7000 to 8000° C. is not in accordance with our knowledge on this subject at the present time. The decomposition of carborundum by means of iron has also, as Mr. Mason states, not been successful. If we critically examine the diamond-producing problem by making a study of the physical and chemical properties of the stone found in nature we will find that the diamond begins to lose its color and transparency at a comparatively low temperature, and with the air or oxygen excluded it is gradually transformed into its coke and graphite modification on more intense heating. In other words it *cannot stand heat*; the diamond therefore must have been formed, even if under high pressure, at a rather low temperature in its original matrix. Its hardness may also be the result of an inherent quality of crystallization, and if the physical data could be secured it would be shown, that such an enormous energy per unit of weight as Mr. Threlfall applied, is not required in the crystallization and production of the diamond. I think that by a new method this crystalline and transparent variety of carbon may be produced, and that those properties will be included that give to this highly-prized jewel its scintillating quality and great beauty. I would be pleased to join forces with Mr. Threlfall to carry the matter out.

San Francisco, December 12.

Reducer in Fire-Assaying.

The Editor:

Sir—In your issue of October 3 appeared an article, 'A New Reducer in Fire-Assaying,' by E. A. Rose. In view of the fact that your journal and others have considered it worthy of reproduction, I think that statements therein should not be allowed to pass without comment. It is scarcely correct to call iron sulphide a new reducing-agent, when we have $Fe_n Sn_{n+1}$ and FeS_2 occurring naturally in ores to be assayed. Also the reducing action of FeS has previously been determined. (See 'The Reduction of Lead from Litharge', *Trans., A. I. M. E.*, Vol. XXXIV, p. 395.) That the proposal to use iron sulphide in place of a carbonaceous reducing agent is new, is not questioned, for the presence of sulphur in an assay is more objectionable than desirable.

The article fails to observe the facts that considerably more gas is evolved from decomposition of the alkaline carbonates than from the oxidation of carbonaceous reducing agents, and that sulphur may be

oxidized to SO_2 or SO_3 . In the oxidation to SO_2 , which escapes as a gas, no reduction in boiling takes place, while to oxidize sulphur to SO_3 requires a basic charge high in litharge, which gives a non-viscous slag, that has as much to do with the decreased boiling and time of fusion as the use of a reducing agent producing no gas. The charge given, using pure silica for ore, and substituting argol for FeS , was fused in a 15-gram crucible without boiling over, which according to the statement made should have given trouble in a 20-gram crucible. The effect of this character of charge on boiling in assaying sulphide ores was noted in the above-mentioned article, in the *Trans.*, A. I. M. E., p. 397. How 15 to 20 minutes is to be saved in the time of fusion is a question, as 25 minutes is ample for ordinary acid ore-charges, and to make a fusion at any reasonable assay temperature in 5 to 10 minutes is preposterous. In what way this reducing agent is to appeal to those who have sulphide ores to assay by the nitre method, where no reducing agent is required, is an enigma.

To sum up: in order to make use of a new reducing agent, which in itself slightly decreases the boiling and time of fusion, Mr. Rose has found it necessary, on account of the properties of this reducing agent, to devise a charge excessive in flux, particularly PbO , which is expensive; and furthermore, causes rapid destruction of crucibles. This high PbO -charge will also give questionable silver results. The advantages are so far outweighed by the disadvantages that they cannot be considered.

E. J. HALL.

New York, January 15.

Note on Drilling.

The Editor:

Sir—Regarding the information asked for by 'Halifax' in your issue of December 5, I would state that for the kind of work that he outlines, and for the depth he mentions (60 ft.), the Chapman boring outfit would be as good as he could get, providing that he has no very hard rock. This system is excellent for holes such as he mentions, and in suitable ground is very fast. If he has hard rock, the diamond-drill is, in my opinion, the best. The diamond-drill can be operated by hand-power for such shallow holes as 60 ft. I regret that I have no data at hand to supply him with, but I am "out of civilization" at the present time. If, as his letter intimates, he wishes to eliminate 'springing' by drilling 3-in. holes, I venture to think that he will regret adopting such a policy, especially if he is engaged in quarrying 'dimension stone,' because by careful springing, he can get a better 'break,' with less shattering of the rock, and with less powder than if he depended on the hole or holes to break the ground. Even if he does not want 'dimension stone,' better results can be obtained by judicious springing, than without. In regard to the charge to be used, it is impossible to state any definite amount on such indefinite data as he gives as to the nature of the rock and the work to be accomplished by the charge or blast. If 'Halifax' can give some idea of the nature of his

rock, and the position it is in (whether it has a face or not) and the purpose it is to be used for (whether dimension stone or not) it would be easier to advise him intelligently. I may add that I have never been connected in any way with any drill-manufacturing firm.

C. R. GENT.

Trimmer, California, January 5.

Progress in Cyanidation.

The Editor:

Sir—It is an accepted principle in our profession that a mining engineer is entitled to have his report published in full or, alternatively, that any extracts from his report be submitted for his personal approval prior to publication. In your case you do me the honor to publish my review of progress in cyanidation at greater length than the manuscript sent you for publication authorizes. Doubtless your reason for this is your knowledge of my views on certain vacuum and pressure filters and the impossibility of communicating with me prior to your going to press. I must therefore take this opportunity of stating that the eulogistic views attributed to me in your issue of January 2, relating to some of the vacuum and pressure filters do not represent my whole views, and, on the other hand, had I decided to publish any statement regarding the Burt filter I should have wished to offset my remarks as to the possible difficulty of effective washing by this filter, by a reference to the remarkably low costs of its operation, shown by the figures published of the work at El Oro.

By a misprint on page 49, the figure 27 is substituted for the correct figure of 25, representing the daily output tonnage resulting from the filtering of pulp of 66% moisture; and on page 50, the $17\frac{1}{4}$ ev. should be $17\frac{1}{4}$ pence, the figure of the cost of crushing by Chilean mills at Pachuca.

ALFRED JAMES.

London, January 25.

[This correction illustrates the need for care in designating money units when speaking of Mexican business; unless otherwise specified it is fair to assume that figures are in terms of Mexican currency, but it is well always to leave no room for doubt.—EDITOR.]

A novel fire-detecting device consists of a fine copper wire core, encased in fusible metal, which, in turn, is covered with insulating material, the whole being contained in a copper tube, about one-tenth inch diameter. This wire is strung the same as ordinary bell wire, or used in short sections attached to terminals and mounted on porcelain blocks in the form of a thermostat. When the temperature rises to the point at which the wire is designed to operate, between 160 and 370° F., the fusible alloy softens and expands through the meshes of the insulation against the inner surface of the copper tube, thus forming a positive and permanent contact between the latter and the core wire, and causing the alarm bells to continue ringing until either the battery is exhausted or the circuit is intentionally broken.

SINKING A WET SHAFT AT TOMBSTONE.

Written for the MINING AND SCIENTIFIC PRESS
By ELTON W. WALKER.

In sinking the main pumping shaft of the Tombstone Consolidated Mines Co., there was struck what is probably one of the largest continual flows of water ever dealt with in the history of shaft-sinking. Pumping from this shaft was started in January 1902, and has been practically continuous ever since. From the beginning 2550 gal. per min. has been pumped. During the past year the average pumped has been approximately 3400 gal. per min. Water was first entered at a depth of 570 ft. below the collar of the shaft, and the mines of the company have now been drained to a depth of 837 ft., so that development is now in progress at a depth of 1000 feet.

While the amount given above represents the total water pumped from the shaft, a portion of it entered at the levels, but it is safe to say that the shaft has been sunk against a continuous flow of from 2200 to 2400 gal. per min. At times this amount has been exceeded, rendering it necessary to provide one or

Steam Pump Co. These pumps have a rated capacity of 600 gal. per minute under a 250-ft. head, and gave excellent satisfaction at all times, suffering little or no damage from blasting; in fact, a couple of these pumps remained in continual operation at the bottom of the shaft for several years without being brought to the surface for overhauling. As there was always the possibility of their being drowned—as occurred in a couple of instances—all nuts that might become loose, and so put the pumps out of commission, were provided with cotter pins in order that the pumps might be kept in operation even if submerged. In one instance, after the pumps had been drowned and were covered with 90 ft. of water, when steam was admitted they started up after a short interval of warming.

The pumps were handled with 5-ton duplex chain-blocks, hung on steel rails, which rested on the timber sets above the pumps. When the pumps are in position the chain-blocks are tightened and support most of the weight of the pumps. The pumps are held to the side of the compartment by small jack-screws placed between the water-chest and the oppo-

Fig. 2.

two extra sinking-pumps in addition to the regular equipment, which consists of four.

The shaft measures 8 ft. 10 in. by 23 ft. 8 in. outside of timbers—10 by 10 in. Oregon pine—and consists of four compartments. Two compartments, 5 ft. 9 in. by 7 ft., were used for the sinking-pumps, piping, etc., and the remaining two compartments, 4 by 7 ft., were used for hoisting purposes. In the end pump-compartment a small cage 24 in. wide was used for the convenience of the pump-men in handling the sinking-pumps, pipes, etc. This narrow width of cage was necessary in order that it might pass between the discharge-pipes of the sinking-pumps, and be lowered close to them. The remaining pump-compartment, in addition to carrying two such pumps at the bottom of the shaft, contained the main discharge-columns from the station-pumps as well as the steam and air-pipes. The inner hoisting-compartment was used in sinking the shaft and the remaining compartment for hoisting from the working levels above. Sinking was done with a cage and car, running on removable guides extending below the timbers. In Fig. 1 is shown the plan and elevation of the bottom of the shaft, together with sinking-pumps, bulkhead, and accessories.

The pumps used while sinking were of the duplex type, 14 by 8 by 12 in., having 8-in. suction and 6-in. discharge, and were made by the Fred. M. Prescott

site side of the compartment. The jacks were fastened to the pumps by a piece of rope so that there would be no danger of dropping the jack into the sump if it should become loosened. Thus there was little or no vibration in the pumps, and they could be easily freed for lowering. To the back of each pump is bolted two hangers of 3½ by 1¼ in. iron, having at the upper end an arm, which is hung on the timbers of the shaft. These hangers support part of the weight of the pump, but are used more for a temporary support while moving the chain-blocks.

Each pump is provided with separate steam, exhaust, and discharge-pipes extending to the pump-station above. In order to facilitate lowering of pumps and connection of pipes, each pipe is provided with a long slip-joint. These slip-joints are always left connected to the pump, and provide for any variations in the length of the sections of pipe used when lowering the pumps. The steam-pipe is provided with a valve at each pump as well as one at the station above. In this way if the pump become submerged it is possible to regulate it from above if the lower valve is left open.

The shaft-sets are 5 ft. from centre to centre and the pumps are lowered one set at a time. The method used in lowering is as follows: The pipe-connections are first loosened to allow the pump to swing free of the timbers, when it is lowered 5 ft. with the chain-

Fig. 1. Shaft-Sinking in Wet Ground at Tombstone.

blocks and hung on the timbers. The expansion-joints, which have a movement of 5 ft., are then pulled out and the pipes connected. At the second lowering the pumps are dropped the same distance, and the expansion-joints are closed together, allowing a 10-ft. section of pipe to be put in place. The third lowering is done with the expansion-joints as at first. At the fourth lowering the 10-ft. section of pipe is removed and a permanent 20-ft. length put in place. This operation is repeated as the pumps are lowered. Ordinarily three or four hours are consumed in lowering, but in an emergency it can be done in considerably less time. In fact, three pumps have been lowered in five hours.

In the earlier part of the sinking, ordinary 8-in. plain-bore rubber suction-hose wound with two layers of a cheap grade of 3/4-in manila rope, to protect the hose from flying rock when blasting, was used; but later a home-made suction-hose (Fig. 2) was devised, which cost about one-third the rubber hose and proved more satisfactory. In making the hose, 8-in. pipe was cut into rings about 1 1/4 in. wide, and these rings were wired together, leaving a space of about 1/2 or 3/4 in. between the rings. The whole was then covered with three layers of heavy canvas sewed on, each layer being made air and water-proof with pine tar. The hose was then covered with rope, as was done with the rubber hose. The total cost of making an 18-ft. length of hose was \$25.50. This cost includes all labor and material except the rings, which were cut from scrap pieces of pipe. The rope and the winding of it are also omitted, as this cost would be the same if a rubber hose were used.

In order to protect the sinking-pumps and shaft-timbers when blasting, as well as to protect the men working below, a bulkhead was used below the shaft-timbers, as shown in Fig. 1. Two steel rails the length of the shaft were hung below the wall-plates by chains and on these 8 by 8-in. timbers were placed close together, leaving an opening through which the hoisting-cage could pass.

On account of the great volume of water it was not possible to remove the suction-hose when blasting, only the lower end being raised from the bottom with chain-blocks. The pumps were stopped when blasting, so that when the holes were shot there was from three to five feet of water covering the holes; this water acted as a cushion and helped to protect the timbers and pumps.

Detailed figures are not available as to the cost of sinking the upper part of the shaft, but the cost of sinking from 879 ft. to 1017 ft. was as follows:

Powder	\$468.24
Caps	25.08
Fuse	141.96
Lumber, lagging, etc.....	1,772.85
Supplies, oils, grease, slickers, boots, etc.	1,357.97
Compressor and drills.....	660.25
Labor (miners)	8,089.95
Labor (miscellaneous)	231.80
<hr/>	
Total	\$12,749.10
Feet sunk	138
Cost per foot	\$ 92.38

Owing to operating conditions, it was impossible

to arrive at the cost of hoisting from the shaft with any accuracy, and for this reason the cost of hoisting is not included in the above.

Effects of forest denudation in China are thus described in the recent message to Congress by President Roosevelt: The floods and freshets which diversify the general dryness, wash away from the mountain sides, and either wash away or cover in the valleys the rich fertile soil which took tens of thousands of years for nature to form; and it is lost forever, and until the forests grow again it cannot be replaced. The sand and stones from the mountain sides are washed loose and come rolling down to cover the arable land, and, in consequence, throughout this part of China, many formerly rich districts are now sandy wastes, useless for human cultivation and even for pasture. The cities have been, of course, seriously affected, for the streams have gradually ceased to be navigable. There is testimony that even within the memory of men now living there has been a serious diminution of the rainfall of northeastern China. The level of the Sungari river in northern Manchuria has been sensibly lowered during the last 50 years, at least partly as the result of the indiscriminate cutting of the forests forming its watershed. Almost all the rivers of northern China have become uncontrollable, and very dangerous to the dwellers along their banks as a direct result of the destruction of the forests. The journey from Peking to Jeho shows in melancholy fashion how the soil has been washed away from the whole valleys, so that they have been converted into deserts.

Coal in the Philippines is found on the islands of Cebú, Batán, and Polillo. The Lantauán field on Cebú, is characterized by thick veins of bituminous coal exceedingly low in ash and sulphur, but also low in fixed carbon, the moisture being as high as 17%. Similar comment will apply to the coal of Batán, except that the seams are thinner and more dislocated by faulting. The volatile hydrocarbons in this coal average about 42%, showing it to have superior value as for gas production. In fact this characteristic applies to all the Philippine coals, the Polillo coal, for example, having the composition:

	%
Moisture	5.58
Volatile hydrocarbons	41.20
Fixed carbon	49.15
Ash	4.07
Sulphur	0.29

Cocos island, a possession of Costa Rica, lying about 400 miles off the coast in the Pacific Ocean, has been the scene of many fruitless efforts to find buried treasure. It is probably the most noted treasure island in the world. The basis for this reputation lies in valuables from royalist families in Peru, secreted there in the first decade of the nineteenth century. Another story affirms that a second treasure was buried on Cocos island by the crew of the barkentine *Mary Dyer* in 1835. Within the year just past one English expedition searched the island, and now another is being organized in New York under Lieutenant Rodger and L. H. Andrew.

SUCHEZ DE BOLIVIA HYDRAULIC MINE.

Written for the MINING AND SCIENTIFIC PRESS
By W. E. GORDON FIREBRACE.

In the Canton of Pelechuco, Department of La Paz, Bolivia, is situated the largest auriferous gravel bank known in South America. It is called Suhez de Bolivia in contradistinction to another similar but smaller gravel deposit known as Suhez del Peru.

Suhez de Bolivia is as well known to South Americans as San Antonio de Poto, and like the

Clavijo Ditch From Reservoir to Pressure-Box.

latter it has yielded immense quantities of gold in the past. Tradition has it that these gravel banks supplied a great part of the gold of the Incas. It is on record that from the date of the conquest of Peru by the Spaniards down to the year 1761 large numbers of gold washers were employed, under Spanish direction, on the Suhez bank, and from the

House Built by Clavijo in 1826.

enormous quantities of old tailing to be seen it is evident that many thousands of people must have been engaged in the work. The rising of the Indians against their Spanish masters occurred in 1761, when the entire white population was massacred, and all records pertaining to the working of Suhez were lost. It was not until the year 1826 that Suhez received further attention from the gold-seeker. In this year three brothers, by the name of Clavijo, commenced work on the bank. They constructed a reservoir, which to this day bears their name, made canals and built houses, and during the 20 years they were operating, extracted large quantities of gold. After this the property seems to have been neglected

for some years, and was acquired by the present owners in 1890. An installation, consisting of a hydraulic giant and a few hundred feet of piping, was rigged, and water brought to the bank under a head of 400 ft. The results obtained were highly satisfactory, but a difference of opinion between the proprietors caused the cessation of operations.

The formation of the Suhez bank is partly glacial and partly alluvial. It is what is known as channel gravel, and owes its origin to the filling up of a wide deep valley with the detritus coming from the disintegration of the mountains which were constantly being eroded by glacial and other agencies. The mountains are composed of Silurian slates, and this formation is intersected by innumerable narrow quartz veins, many of which are extremely rich in

Bringing Pay Dirt to Clean-up Boxes.

gold. It is from the disintegration of these narrow veins that the gold content of the Suhez auriferous bank has been derived. The deposit is composed of small boulders of slate, quartz, porphyry, and sandstone, cemented by a sandy clay. It is easily disintegrated by water under pressure, and throughout the whole mass, from the surface to the present working level, free gold is disseminated. There does not appear to be any overburden or barren gravel; it all contains some gold; some places are richer than others, and like other large gravel deposits in this region. Suhez has several rich *veneros* or pay-streaks running through it. The gold is exceptionally pure, and sells at \$20.50 per ounce. It occurs as dust, flakes, scales, and nuggets; it is not uncommon to unearth nuggets weighing as much as one ounce.

Suhez is situated at an altitude of 15,000 ft. above sea-level, and is just within Bolivian territory, the boundary of the concession being the imaginary line which serves to divide the Republic of Peru from that of Bolivia. One would naturally assume that the difficulties of working would be enormous at such

an altitude, but this is not the case. Although Suhez is mostly above the line of perpetual snow, water never freezes, and there is nothing to prevent sluicing for at least 9 months of the year. At the foot of the Suhez bank is Lake Suhez, into which the tailing has been dumped in the past. This lake is large and deep, and can be utilized as dumping ground for many years to come. The quantity of gravel available for washing appears to be almost unlimited, and several engineers, who have professionally visited the property, are unanimous in stating that 400,000,000 cu. yd. can in no way be considered an exaggerated estimate.

As regards the average value per cubic yard of this enormous mass there is not the same unanimity of opinion, although all agree that there is sufficient gold to pay handsomely. The lowest estimate is 16c. per cubic yard, and the highest 33c. The result from the washing of many thousands of yards of gravel is reputed to have been equal to the higher estimate, but in my opinion it would be more prudent to put the average value per cubic yard at 20c. Working costs should not be higher at Suhez than in California or New Zealand, as labor is much cheaper. The daily wage paid to ordinary native laborers in this district is 20c. Overseers and mechanics receive a few cents more. The native is fairly intelligent and soon masters the work required of him, and can easily be taught to become an expert nozzle-man. The present water-supply is obtained from the melting of the snow, and does not permit of working for more than a few weeks in the year. These waters are collected in the Clavijo reservoir; from there they are conducted by a ditch to the pressure-box which is about 400 ft. above the giant. No attempts in the past have been made to improve the water-service, although it was known that there was in the district a considerable quantity of water, at a sufficiently high altitude, to be brought to the property. This supply of water has now been definitely determined as being 1500 miners inches, and it is confidently anticipated that a further 1500 miners inches will be available. Some of this water will have to be brought a considerable distance, but as there are no depressions to be crossed it can be conducted by ditches, the construction of which will not be a costly undertaking. The best way to reach the property is by way of Mollendo, a port in southern Peru; thence by train by way of Arequipa to Puno; from Puno by steamer across Lake Titicaca to Huaicho; and then by mule to Cojata and Suhez. If the construction of the road, contemplated by the South American Co., which has lately acquired San Antonio de Poto, is carried out, it will be of great advantage to Suhez, as this road will pass close to the property and will permit of the transport of supplies by carts or traction engines. At present all material must be transported on mule-back. At Suhez are a comfortable house, store, workshops, and other buildings, and the property is only 15 miles from Poto, at which place is a telegraph office. An English company has taken an option and engineers are now on the way to examine the property.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

D. J. S., Denver: Specimen too small for satisfactory examination; probably an indurated shale but with a greenish color tinged with brown as though limonite and chlorite were present in considerable amount.

Bear's Nest lies next to the Paris claim of the Alaska Treadwell Mining Co., on Douglas island, Alaska. One has proved as big a fiasco as the other a treasury. In 1896 the Bear's Nest was the scene of an impudent scheme of deception, warranting a re-christening of the mine to Mare's Nest. An option was taken and a company formed. An adit had cut the lode, which resembled that of the Treadwell mine in everything except the gold content. Ore from the big open-cut of the Treadwell mine was brought by night to the Bear's Nest and thrown on the dump, so that samples taken next day yielded good assays. Later, four diamond-drill holes were sunk from the adit, and these are said to have been 'salted' with gold chloride. The first trick fooled the experts representing English capitalists, and the second deceived some German investors and their advisors. Another version states that holes were dug in the outcrop and filled with ore from the Alaska Treadwell mine. When milling was started, it was found that a trick had been played, thereupon a diamond-drill hole was put down alongside the bore previously made and it proved barren. The original hole was reamed out and the ore found to assay nothing, although the core had assayed well. Nothing has been done since then, although the amount of sane prospecting done at this end of the lode is insufficient to prove non-persistence.

New Chinese weights and measures just put into effect are defined in terms of the metric system. The new unit of length is the 'tchi,' equivalent to 32 centimetres; the unit of capacity is the 'to,' equivalent to 10.355 litres; the unit of weight, the 'lian', equivalent to 37.301 grams. About a year ago the Chinese board of revenue and commerce was authorized to devise and put into effect a new system of weights and measures throughout the Chinese Empire. *Mining World.*

CORNISH PUMPS AND PUMPING ENGINES.—I.

Written for the MINING AND SCIENTIFIC PRESS
By HENRY F. COLLINS.

The following remarks, based upon practical experience in the working of large Cornish pumps in Cornwall, Wales, Spain, and elsewhere, were suggested by a recent discussion in the MINING AND SCIENTIFIC PRESS, in particular by a letter published in the issue dated October 24, 1908, from my friend E. R. Woakes, whose statements I can corroborate from personal observation. At the outset I think it is advisable to draw a clear distinction between the usual Cornish system of pumping, that is, Cornish pitwork, and the Cornish pumping-engine, which is the single-acting engine briefly described in Mr. Woakes' letter. Cornish pitwork may be operated by a Cornish engine, but it may also be operated by an inverted single-acting beam-engine, simple or compounded, by a double-acting beam-engine and fly-wheel, or by a compound horizontal engine, the reciprocating motion in this last case being transferred from a horizontal to a vertical direction by means of 'angle-bobs' or quadrants. There is, however, an important difference in the pitwork itself when a horizontal engine is employed, namely, that whereas in the original Cornish system and in all the variants that employ vertical cylinders and a walking-beam, only one main rod with its set of plungers is used for each engine; when a horizontal engine is employed it becomes convenient and economical, if not absolutely necessary, to employ two main rods and sets of plungers for one engine. This plan offers both advantages and disadvantages: on the one hand the pumping capacity of the plant is doubled for a given size of engine, since useful work is done upon both strokes; this naturally makes for economy in capital outlay, as does also the fact that the engine-house is of a less expensive form and less expensive construction than is required for engines of the vertical type with walking-beams. On the other hand the 'angle-bobs' or quadrants with their foundations have to be made so massive as practically to offset any saving on engine-house and foundations, and go some way toward compensating for the heavy cost of the extra engine required to work the second rod. Again, however, the further fact must be considered that with a horizontal engine and quadrants it is easy to arrange the two rods side by side in a pumping compartment of reasonable dimensions, whereas in cases where the quantity of water to be raised is more than can be conveniently handled by a single main-rod with its set of plungers the two vertical engines (on opposite sides of the shaft) required in the single-rod system would close it in very awkwardly and render pitwork changes exceedingly difficult unless the shaft were reserved for pumping only. In practice, the maximum amount of water that can be continuously raised by one rod and set of pitwork from a great depth may be put at about 1200 imperial gallons per minute or say 1,700,000 gallons (8500 short tons) per 24 hours, which is what can be done with 24 in. work, anything over this size being unhandy for rapid changes, particularly as regards sinking lifts, for

which 19 or 20-in. buckets, valves, etc. prove to be convenient.

Let us then consider the term 'Cornish pumping' to mean pumping by means of plungers in series attached to a reciprocating main rod, each plunger drawing from the cistern into which the water is discharged from the lift below and delivering to the next above in the same manner. The special advantages of Cornish pumping may be summarized as follows:

1. Reliability: Having a well erected system of Cornish pitwork kept in thorough order, a harassed superintendent can sleep at night, sure that no trouble with the pumping is likely to mar his rest. Given proper erection in the first instance and careful supervision afterward, sudden stoppages of the whole pumping plant, due to failures of main-rods or of connecting rods to balance bobs, etc., will not happen more than about once a year. Changes of leaky valves and buckets, worn brasses, etc., can be foreseen and indeed form part of the regular routine; the aggregate amount of stoppage entailed by such changes is barely a tithe of that necessary with direct-acting underground steam-pumps. No one who has had practical experience both of the troubles inseparable from direct-acting steam-pumps underground and of the smooth working of large Cornish pitwork could ever contemplate giving the preference to the former for other than temporary or emergency purposes, the only advantage of the direct-acting pump being its low first cost.

2. Flexibility: Seeing that large Cornish pitwork when operated by an engine provided with cataraet gear can be easily regulated to run at $1\frac{1}{2}$ or even 1 double stroke per minute, and that if in good condition it can safely run for long periods at 7 or even 8 strokes, it is evident that a wide range of capacity is readily obtainable—and with practically no loss of efficiency save the increased proportion of the total heat lost by radiation at the lower speeds, and the increased leakage through the valves. This is an important advantage as compared, for instance, with electrical pumps, the efficiency range of which is so limited that such a degree of flexibility as that mentioned can only be obtained by multiplication of small units.

3. Durability: No other type of pumps or of pumping-engine has anything like the life of the Cornish pumps and engine. At the present moment in Cornwall and Wales numbers of Cornish engines with 60 to 80-in. cylinders are being operated although from 40 to 50 years old, while one engine can be cited at East Pool mine that was built in the year 1834 and has therefore been working more than 75 years, the only material renovation in all that time being the replacement of the 60 in. cylinder with its valves, nozzles, etc., by a new 70 in. cylinder about 20 years ago. This is sufficient testimony to the durability of the Cornish engine. As to the pitwork, it often becomes rusted and corroded by acid mine-waters, but otherwise wear and tear is at a minimum, the slow motion, of course, being a great advantage from the point of view of durability. The iron-work of valves and buckets apart from hoops

and gearing never wears out and where the water itself has no corrosive action the metallic seatings of the valves require re-facing only at long intervals, while the plungers themselves when properly packed will work for many years under favorable conditions, with scarcely any appreciable wear.

4. Adaptability to sinking against water: This fact, mentioned in the recent correspondence in this journal, is in reality the crowning glory of the Cornish system of pitwork. Even when the quantity of water issuing from the bottom of the shaft is only moderate, say 300 gal. per min. and upward, it is both cheaper and more convenient to sink by means of a bucket-lift attached to the main rod rather than by means of a direct-acting sinking-pump, for which not only has a rising main to be run up to the cistern of the station-pump, but a separate steam-pipe has to be brought down and usually a separate exhaust-pipe has to be carried up. When, however, the quantity of water in the bottom of the shaft increases to 600 or 700 gal. per min. there can be no question of the greater economy and convenience of the Cornish system. Not long ago I had to sink a large shaft, which was already down 820 ft., to a farther depth of 400 ft. without interfering with its use as the main working shaft of the mine. The in-coming water of the mine varied between 350 and 500 gal. per min., according to the season, but the country rock was so jointed that the moment sinking began the whole of the water dropped to the bottom of the shaft while more came in, and sinking thereafter had to be continued against the increased quantity of 600 to 700 gal. per min. This water was handled without any special difficulty by means of a succession of 18½ in. bucket-lifts hanging from jack-screws and worked by bucket-rods attached to the main-rod in the ordinary way, these being sometimes of 8 in. pitch pine and sometimes of 3¾ in. round iron. About half way down, namely at 950 ft. from surface, a new 18¼ in. plunger was put in and the sinking again continued with bucket-lifts in series, a third plunger being put in at 1150 ft. The shaft was 22 ft. by 7 ft. 6 in. inside timbers, the rock a very hard diorite somewhat jointed, and the total cost of sinking over the whole distance averaged only \$75.91 per ft., including \$22.84 per ft. for the timber—9 in. sets and 1¾ in. lagging, all of pitch pine. The above figure includes the whole cost of fixing and lengthening bucket-lifts, etc., but not the actual cost of pumping the water, this being considered as part of the ordinary mining costs. The operations of sinking and timbering were carried on together and were interrupted several times for various reasons; they took in all about 16 months, the average rate of sinking being thus about 25 ft. per month. Considering the hardness of the ground and the quantity of water to be contended with, and taking into account the further fact that the use of the shaft as the main working shaft of the mine could not be interfered with, this may be considered satisfactory both as regards rate of progress and cost. There is no doubt in my mind that given the heavy water and other conditions, with direct-acting steam-pumps the shaft could not have been got

down so rapidly or at anything approaching the same cost; in fact, without the Cornish pumps the job would have been more difficult as well as much more costly. In this sinking the actual 'clacks' of both buckets and valves were of the ordinary butterfly type faced with leather, but the gearing of the bucket-forms in the working barrels was of a special gutta-percha composition that far outlasts leather, particularly where much grit is present. In the plunger-lifts large double-beat valves were employed, the actual 'beats' being rings of the special gutta-percha composition above referred to, let into grooves cut in the valve-faces. These rings, when pumping moderately clear water, were found to last on an average 8 to 9 months before they commenced to leak perceptibly, and their replacement was only a matter of two or three hours work.

In its efforts to reduce the number of fatalities in coal mines, the United States Geological Survey, through its Technologic Branch, is about to establish rescue stations in the principal coalfields of the country, in addition to the experiment station at Pittsburg. The new stations will be at or near the greatest centres of accidents, and it will be the purpose of the experts to teach the miners and mine bosses how to use the most approved apparatus for mine rescue work. Government engineers, thoroughly trained in the use of rescue apparatus, will be assigned to these stations, and they will be ready at a moment's notice to go to the scene of any disaster in their district. The experts will be equipped with oxygen helmets, which will enable them to enter a mine at once, even though it be filled with gas or smoke. These stations will also be headquarters for the study of the waste of coal in mining, one of the important problems before the Geological Survey. The coal mining companies are to be invited to send picked men to these stations, where they will be trained in the use of oxygen helmets. It is not the purpose of the Government to engage in general rescue work, but to demonstrate this apparatus until such a time as the mine owners have thoroughly trained rescue crews at their mines. All of the rescue stations are to be in co-operation with the mine owners and State Geological Surveys. One station will be at Urbana, Illinois, in connection with the University of that State. A second will be at Raton, New Mexico. Another station is suggested for Salt Lake City, Utah.

On the southeast coast of Alaska, erosion by the movement of snow has sculptured the mountain masses into pyramidal forms with three to five faces. In these the snow has hollowed cirques that now serve as the gathering places for the névé feeding the glaciers. Between the cirques the rock has been worn to knife-edges or arrêtes, while the central pyramid survives as the hard core of a big mass. This can be expressed also thus: The accumulating snow flowing as a glacier wears a hollow in the mountain side, ending in the formation of cirques between which the corroded rock survives as a comb or arrête.

ORE-WASHING AT CRIPPLE CREEK.

Written for the MINING AND SCIENTIFIC PRESS
By S. A. WORCESTER.

The larger portion of the rock hoisted from the mines of the Cripple Creek district is separated into four products: waste, ore, screenings, and slime. In a few cases a fifth product, called middling, is separated. One or more of the large mines estimate that nearly 85% of their rock is thrown on the dump as waste after sorting, leaving but 15% ore. Hence it happens that a mine shipping 15 tons of ore daily may have to hoist 100 tons of rock, in order to maintain its output. This explains the immense size of some of the larger waste-dumps of this district, which includes, with their immediate surroundings, the towns of Cripple Creek, Victor, Elkton, Anaconda, Goldfield, Independence, Altman, Cameron, and Gillette. In these mines practically the entire vein is broken and sent to the ore-house for sorting, and where the vein is too narrow for a stope or drift, enough waste is shot down to give the necessary width, and all of this rock is sent through the ore-house. In the most economical plants the ore is automatically dumped by the mine-skip through suitable deflecting spouts to any one of several grizzlies. Beneath the grizzly, which is inclined at an angle of 45°, and has bars spaced from 1½ to 4 in. apart, is placed the screen, of ¼ in. wire-cloth with ¾ to 1 inch openings. Middling, or the product which passes the grizzly, but not the screen, is usually allowed to fall with the crude ore from the grizzly into the crude-ore bin, in which case the grizzly is used only to protect the screen from damage by large rocks, and the screen-bars are widely spaced. In some cases a diagonal spout or trough is placed beneath the screen, running from one corner to the opposite one. The spout is very narrow and diverts a small proportion of the screenings into a bin or box. This sample is assayed, and in some cases shows such low value that the screenings are thrown on the dump, as otherwise they would be shipped at a loss to the operator.

It is characteristic of nearly all of the ores of this district that the gold is found principally in streaks of friable material lying between the harder and the barren gangue. In the operations of mining the greater part of the gold-bearing material is broken comparatively small, leaving the waste in coarser pieces. By passing the material over a screen of suitable size of opening, the richer may be separated from the leaner ore. Considerable profits have been made by lessees by merely screening old dumps which had not been previously screened. The fine material which adheres to the gangue, and is removable after screening only by washing, or some equivalent operation, has still higher gold-tenor than the screenings. At the Strong mine, which is an exception to the general rule, in that the ore exceeds the waste in quantity, the sorting, after screening, is done on low tables, using shovels or forks for handling the ore, and picking out the waste by hand. The waste is thrown into cars and trammed to the washer. A primitive method of screening which is used by some

of the small dump lessees, consists in shoveling the rock onto an inclined screen in the same manner in which sand is ordinarily screened for making mortar. The second step in the process of preparing ore for shipment is by washing at some mines, and by dry-sorting at others. Where specially accurate sorting is desired, the preference seems to be for washing, for the reason that the various minerals show much more distinctly when the rock is wet, and has the dust removed from its surface. At mines which wash only the waste, the sorting tables are placed at the gate or mouth of the crude-ore bin. The table has a steel or cast-iron top from 3 ft. square to 3 by 4 ft. in size, and from one to four men work at each table. At the larger plants the ore and waste are raked or scraped over the edges of the tables into separate spouts leading to ore and waste-bins, or perhaps to washers. At the Portland, Findley, and Golden Cycle mines, the ore is scraped over the front edge of the table into spouts leading to the ore-bins and the waste is scraped over the sides into spouts leading to the washers. A small piece of sheet-steel is used for a scraper. At the Elkton, Cresson, Granite, and Abe Lincoln mines the crude ore is screened by revolving cylindrical screens, and washed by the Crane patent revolving cylinder washer. This cylinder is inclined, with its lower end below the surface of the water in the slime-tank. The cylinder is perforated with about ½ in. holes, and has an interior spiral which carries the rock from the lower or receiving end to the upper end, and delivers it on a picking or sorting belt. This belt is from 30 to 50 ft. centre to centre, and has a number of spouts beside it, into which the sorters throw the ore, allowing waste to pass on over the end of the conveyor to the waste-bin or car. While the ore is probably washed more thoroughly by the Crane washer than by the more commonly used spraying device, the initial cost of the Crane machine prevents it from being more generally used. Its washing is more thorough, for the reason that it turns the rock over and over, subjecting all sides to the action of the water, while in the spraying-washer the ore merely slides through the machine, without turning over and over, and with very little of the active rubbing which occurs in the cylinder machine. The spraying washer, in its ordinary form, consists of a spout or chute placed usually at the mouth of the crude-ore bin, but in some cases having the ore or waste brought to it by spouts. It has a steel-plate bottom with ⅜ to ½ in. perforations closely spaced and with a slope or fall of two thirds of its horizontal length. A gate at the lower end of the washer is opened periodically by the sorter or trammer, allowing a small quantity of ore to pass through onto the sorting table, or if waste is being washed, the gate delivers it to a car, which is trammed to the waste-dump. The slime and fine material are washed through the perforated bottom-plate into tanks, in which they are deposited. A pump returns the water to the spray-pipes with sufficient pressure to give the issuing jets considerable force, in order to make the washing effective. Usually a rotary pump, driven by an induction motor, is used, but in some cases steam or other pumps are employed. The settlings are

shoveled out of the tanks periodically and dried either by steam-heat or in pans heated by fire. At some plants, as for instance at the El Paso mine, after equipping all crude-ore bins with spraying washers, wash only certain classes of ore, shutting off the water from one or more washers and allowing the ore to pass through dry. The spraying washers used at the Findley and Strong mines have reciprocating perforated pans with a slight inclination. The waste rock is fed to the upper end of the pan from bin-gates, and is sprayed during its passage to the lower end. The slime passes through the perforations into settling-tanks beneath, and the washed rock drops from the lower end of the pan into the waste-bin or car. The simplest form of washer uses an oblong box, having a perforated plate resting a few inches below the surface of the water with which the box is nearly filled. The rock is shoveled onto the plate and moved around in the water with a fork or shovel until washed, the slime passing through the perforations to the bottom of the box, which is cleaned periodically and the slime dried and sold. This crude arrangement is used, of course, only on a small scale. In designing a surface-plant for hoisting ore and preparing it for shipment, it is well, in view of the processes which have been described, to give the ore-house ample height, so that the waste may be delivered at a sufficient elevation to allow of dumping for a considerable time. It is also well to consider the advisability of having the mine-skip dump directly, by suitable spouts, into the ore-house, thus eliminating all expense in transporting from the shaft to the ore-house. Where a large tonnage is handled this item becomes one of considerable importance. The objection which may be raised, that fire in the ore-house would endanger the mine, can be easily overcome, for example, by fire-proof doors. The importance of thorough washing is illustrated by the fact that one large mine has made for some years a constant practice of washing all waste in three successive spraying washers, and saving slime of considerable value by the third washing. A considerable number of old waste-dumps have been washed over with success, in some cases tramping the rock to a stationary washer of the spraying type, and in others using a portable machine having a cylinder revolving in a tank, similar in arrangement to the Crane washer, but small and light enough to be moved and kept within easy shoveling distance of the pile to be washed. The rock is shoveled directly into the receiving end of the cylinder and delivered at the other end to a car, which is trammed away and dumped. Power for rotating the cylinder is furnished by a 2 or 3 hp. induction-motor.

The ore-house and head-frame are of recent design, and embody some of the best features of current practice in small plants. The skip dumps its contents on a short slope, from which they fall on the deflector. This deflector or door may be swung through an angle of 90°, so as to direct the crude ore to either one of the two grizzlies. This arrangement contemplates the addition of a third unit, including grizzly, bins, sorting table, washer, etc., at a future time. As

it will be necessary to handle waste, without sorting, when development is in progress in the mine, a waste-bin is provided, close to the head-frame, and a switch, operated by the engineer, is arranged to dump the skip-load into the waste-bin. The skip is so designed that the box or body can be easily and quickly removed and hung up out of the way. A removable cage-floor is then placed on the cross-bars at the bottom of the skip-frame, converting it into a cage for conveniently handling men, rails, timbers, etc. In this plant middlings are not separated, but pass over the screen and into the crude ore, and are washed and sorted. Ordinary mine cars stand on the sorting-room floor, within easy reach of the sorters, who throw the waste into the cars and tram it to the waste-dump, while ore is scraped over the edge of the table into the vertical spouts leading to the bins below. The screens are adjustable to varying angles, so as to be effective for either dry ores or those which, being wet and sticky, require a steep pitch in order to prevent clogging. The screening-bins have long spouts passing down the corners of the ore-bins and delivering screening at the same elevation as the ore, for shipment. The settling tank for the slime from the washers has several unusual features. Its construction is very cheap, it being merely nailed together, without any tonguing and grooving, the lumber being dressed on one side only and no rods are used. This rough and cheap construction has proved thoroughly practical for slime-tanks of moderate depth. The arrangement of baffles for minimizing the speed of the entering and out-going water and slime and for preventing any rapid currents in the tank, makes it an effective settler and reduces the size and expense of the tank for a given capacity. A steel-plate lining, at one side of the tank, forms a steam heater, through which the exhaust from the hoist passes, preventing freezing in winter, and giving more effective washing than can be accomplished with cold water. An exhaust steam drier, consisting of a shallow wooden steam box, covered by steel-plates, on which the slime is dried, is placed in the space under one screening bin, not occupied by the slime-tank. Light for the sorting tables comes from the top, side, and ends of the sorting room. All bin-bottoms slope 45°, so that no shoveling or scraping is necessary in order to empty the bins. All posts rest on concrete piers, with $\frac{3}{4}$ inch dowel pins.

The Swelling of Cast-Iron.—Many tests have been carried on to ascertain the percentage of swelling that takes place in cast-iron and these tests have shown the possibility of producing a swelling of as much as 40% in the volume of cast-iron, by heating and cooling. A bar measuring 1 in. square by 14.8 in. long was heated and cooled in a gas furnace 27 times, the high temperature being 1450° F. Careful measurements then showed the bar to be 1 $\frac{1}{8}$ in. square and 16 $\frac{1}{2}$ in. long. It is thought that this fact explains many of the difficulties experienced with cast-iron fittings for use with superheated steam, where the same sort of alternate heating and cooling takes place.—*Power and The Engineer.*

A ROCKER.

Written for the MINING AND SCIENTIFIC PRESS
By DOUGLAS WATERMAN.

This machine when used in testing placer-ground should be constructed of light material, so that it may be carried easily from place to place, and should be of such design that it will save all the gold. To get the best results the material retained in the rocker should be loose, to allow the gold to settle to the bottom. Insufficient grade will cause the material to pack and the fine gold will wash over the lip. If the rocker be unnecessarily heavy, or if it move through a large arc, the operator is unable to give it the agitating motion required to prevent packing, and loss of gold results. Experience indicates the best design, but it rarely happens that the engineer avails himself of the opportunity to record dimensions for future use. This has led me to pre-

great economy where water must be brought from a distance, as the same water is used over and over again. Where accurate results are required it is advisable to re-treat the tailing; thus any gold carried over by muddy water in the first washing is finally recovered.

A clean-up is made at intervals, the frequency depending upon the richness of the ground, and upon the character of the material washed. Ground containing much clay necessitates a frequent clean-up, as the sticky material soon becomes packed in the rocker. The hopper is removed, and the gold on the apron is washed into the rocker. Packed gravel and concentrate on the rocker-bottom is thrown back to the head, and with clean water and rapid agitation the coarser material is washed over the lip. A second hopper with fine holes is then employed to remove all but the gold and fine concentrate. Skilful rocking at this point separates the gold from the

A Typical Rocker.

sent the accompanying drawing of a Chinese rocker of excellent design, in the hope that it may be of assistance to others.

The Chinese miners in California are expert in the use of the rocker; their methods are as follows: The machine is placed near the shaft or cut, and is carefully adjusted to the proper grade. This is accomplished by blocking the frame or bed on which the rocker rests. It is usual to allow the material to cover a little more than half the bottom of the rocker in the process of washing. The frame is weighted with stones to prevent it moving. A hole is dug under the lip, and another at the head of the rocker; this second hole is made slightly deeper than the first, or, if the contour of the ground will permit, it is at a lower level; and the two are then connected by a shallow trench.

After partly filling the hopper with gravel the operator seats himself beside the rocker, dipping the water from the lower hole with his right hand and rocking with his left. This operation is apparently a simple one, but it requires practice to handle the dipper and at the same time impart an even motion to the rocker. After passing through the rocker, the water falls into the upper hole, returning through the trench to the operator's hand. This effects a

black sand, the particles of gold being collected and picked up by a quick motion of the scoop.

Prediction of the recent Italian earthquake was made by Frank Alvord Perret, according to T. A. Jaggar, Jr., writing in the *New York Evening Post*. Mr. Perret, who was decorated with the Crown of Italy for his service to science and to humanity on Vesuvius in 1906, wrote in the *World's Work* of November, 1907: "By the rational methods of scientific research, we know that a great eruption of Mt. Etna is impending, the only uncertainty at present being which side of the mountain will break open." Great volcanic eruptions are preceded by great earthquakes, and the Messina disaster of December 28 comes on an earthquake date ("terrestrial maximum of gravitational stress") actually platted in advance by Mr. Perret on his diagrams for 1908. Like F. Omori, the great Japanese seismologist, he is a man whose whole time is unselfishly devoted to these studies.

Junin is the most important mineral producing department of Peru. The chief products in 1907 were: gold, 44.3 kilograms; silver, 108,026 kg.; copper, 34,302,000 lb.; coal, 169,368 tons; lead, 4970 tons; antimony, 432; bismuth, 48; and vanadium, 73 tons.

COMPANY REPORTS.

YUKON GOLD.

S. R. Guggenheim, president of the Yukon Gold Co., under date, of January 30, 1909, has issued a letter to the stockholders giving a general statement concerning the progress of operations in the Klondike district of the Yukon Territory. He says, in part:

At the time our engineers made their first examination in 1905, the placer fields of the Yukon were fast becoming depleted; the volume of gravel workable at a profit by hand-method was rapidly being reduced, and the cost of working, under the methods then in vogue, precluded the extension of the operations to lower-grade material. The principal factors making toward the high cost were:

First—The disconnected nature of the holdings (the claims being not over 500 ft. in length and owned largely by individuals), which reduced the workings to a number of small-scale operations, and prevented systematic mining upon any larger scale.

Second—The scarcity of water. The miners, both those working upon the creek levels and those upon the bench and hill deposits, were entirely dependent upon the rainfall for their supply of water. As the snow and rainfall is very irregular in the Klondike district, a corresponding irregularity entered into the mining operations, with a consequent increase in cost. No large-scale hydraulic operations were possible with such limited and intermittent water-supply.

Third—The high cost of fuel, labor, and supplies. Wood fuel is available in the Klondike for mining purposes, but its cost is high and constantly increasing. Coal is to be had, but it is as expensive as wood. Labor is high, due to the short season for outside work, and supplies expensive because of high transportation charges, and the small and irregular character of the purchases.

Our investment in the Yukon was based upon three fundamental hypotheses:

First—That we would be able to acquire large and connected blocks of ground for systematic working.

Second—That we would be able to secure and make available at sufficient elevation a continuous water-supply.

Third—That we would proceed to equip the properties with the most modern mechanical appliances, such as dredges and elevators, for handling the gravels upon a large scale and at a low cost, depending for power not upon local fuel, but upon electrical energy generated in our own hydro-electric plant.

All of these things have been accomplished. At the present time our holdings amount to about 90% of the claims located on the hills and creek bottoms of Bonanza, Bear, Hunker, and Eldorado valleys, which were wanted for the enterprise. These properties have been acquired mainly by outright purchase, although in some cases, where un-acquired claims adjoin the properties of this company, advantageous working agreements have been made with the owners.

Early in 1906 construction was begun upon a system which will insure to the Klondike a continuous water-supply for all time. This was in itself a tremendous undertaking, involving the diversion of Tombstone river (the main right fork of the Twelve-Mile), carrying it a distance of about 62 miles by flume, ditch, and pipe-line, through a country which was an absolute wilderness when our engineers first went upon the ground.

Simultaneously with the construction of the water system, a hydro-electric power-plant was installed on the Little Twelve-Mile river, capable of delivering 2000 hp., which is transmitted to the placer fields by a high-tension line, 36 miles straight across country, with three sub-stations and 18 miles of secondary line. A huge dam has been built at the head of Bonanza creek to conserve the water of the upper Bonanza watershed for use upon the company's Bonanza and Eldorado creek properties.

Operations in the latter part of 1908 demonstrated the entire success of this method of mining, as applied to the gravels of the Yukon. The difficulties due to frozen ground

have been overcome within the limit of a reasonable working cost. Three mechanical elevators were installed, two of which were put into operation during the season of 1908. It is a great pleasure to say that the mechanical elevators, electrically driven, which were designed by our own engineers and used here for the first time in any country, were entirely successful. Since acquiring the properties in the Yukon, we have carried on hydraulicking to a limited extent, and dependent upon the local intermittent water-supply. The operations have shown a profit, and have proved not only the value of the gravel, but also that a very low working cost can be reached.

In the season of 1909 we expect to have the equipment working up to at least one-half of its ultimate capacity. In the season of 1910 we fully expect to show a production which will make the Yukon Gold Co. take rank as one of the largest gold mines in the world. We had only proved our holdings in part, first, because of the advisability of concentrating our engineering staff upon the installation of the present equipment, and second, because of the expense attendant upon the thorough prospecting of ground in the North. Our engineers having reported that we now have nearly \$40,000,000 net in proved ground, which is approximately 100% profit on the shares at par, and provides for many years dividends, we concluded to postpone further prospecting of our holdings, until our present plant and equipment are running to full capacity.

The shareholders will be interested to know that a large majority of the outstanding capital stock of the Yukon Gold Co. is owned by the Guggenheim Exploration Co., whose engineers have under their direction the equipment and operation of the properties. The Guggenheim Exploration Co. has financed the scheme from its inception, justifying its investment by the conclusions of its engineers after rigid examination and exhaustive reports. That they are satisfied with their investment is evidenced by the fact that they have not disposed of a share of their holdings. For the past season final results have not as yet been actually determined, but incomplete figures show that the net earnings to December 31, 1908, will be about \$550,000.

Our engineers have estimated the probable earnings for 1909 at from \$1,100,000 to \$1,500,000. The wide difference in these figures is due to the unknown factors entering into the water-supply, and the uncertainties attendant upon the first operation of a new ditch line of such length, and constructed under such difficulties. If we have comparatively few washouts or accidents on the main ditch system or the equipment, our earnings will probably reach the higher figure. In 1910 the net profits of the company should be from \$2,000,000 to \$2,500,000, and in 1911 and thereafter, \$2,500,000 net per annum should be the minimum.

The fact is that the directors of the Guggenheim Exploration Co. feel that they, as pioneers in the industrial development of the North, have taken the first steps toward the establishment of a permanent and substantial mining industry in the Yukon Territory and Alaska. The day of the small operator has come and gone, and in his place entered the corporation, to do the things which few individuals, having the means, would care to undertake; that is, to supply sufficient capital for the development of the resources of the country and make its mining future definitely assured. It required courage to make such an investment, running well up into millions of dollars, but the directors feel that the money and time they have expended in developing the resources of the North, will ultimately result in a large profit to the stockholders of the first company to go into placer mining in this region upon so gigantic a scale. That others will follow in our footsteps we hope and have no doubt, now that we have demonstrated that the frozen gravels can be worked with reasonable operating cost, and in fact that all of the handicaps under which the individual operator labored can be overcome. We feel safe in predicting, therefore, for the future, an immense increase in the gold output of Alaska and the Yukon Territory which naturally will be attended by improvement in local conditions and increasing prosperity.

MINING AND METALLURGICAL PATENTS.

Specially reported for the MINING AND SCIENTIFIC PRESS.

APPARATUS FOR ELEVATING GOLD-BEARING DEPOSITS FROM RIVER-BEDS. No. 910,277. Albert L. Eliel, San Francisco, Cal., and Oscar H. Eliel, La Salle, Illinois.

An open-ended, vertically arranged hollow shaft and a frame in which said hollow shaft is mounted so as to slide and to rotate, in combination with mechanism for moving said hollow shaft vertically, mechanism for imparting to said hollow shaft reciprocating rotary movement, and an air tube connected with the bottom end for introducing compressed air into the hollow shaft when partially submerged.

DISTRIBUTING-VALVE FOR PERCUSSIVE ROCK-DRILLING MACHINES.—No. 910,447. Anthony J. Bant and Henry Gullett, Johannesburg, Transvaal.

In an engine, the combination of a cylinder provided with ingress and egress ports, a piston for said cylinder, fluid distributing means located in said cylinder for controlling ingress and egress of pressure fluid through said ports, a device associated with said piston for operating said means, and adjustable mechanism limiting movement of said means and controlling the operation of said device.

In an engine, the combination of a cylinder provided with ingress and egress ports, a piston for said cylinder, fluid distributing means located in said cylinder for controlling ingress and egress of pressure fluid through said ports, a device associated with said piston for operating said means, and adjustable mechanism for controlling the position of said device.

WELL-DRILLING MACHINE.—No. 910,235. James G. Russell, Stewart, Ohio.

In a drilling machine, the combination with a supporting frame, of a driving shaft journaled in the frame, a drill rope reel extending longitudinally of the frame and having one end thereof inclined downwardly, a derrick arranged near the lower end of the reel and provided with means for

guiding the rope to said reel, a crank secured to one end of the driving shaft, a spudding device carried by the crank, a roller journaled in the frame on one side of the rope reel and adapted to guide the rope from the reel to the spudding device, and means for imparting movement from the driving shaft to the rope reel.

ELECTROMAGNETIC STAMP-BATTERY.—No. 910,834. James P. Lynn, Trafalgar, Kalgoorlie, Western Australia.

No. 910,834.

No. 910,253.

In an electro magnetic stamp battery, stamp stems having enlarged portions, sleeves each carrying a magnet in which said enlarged portions reciprocate, and threaded rotatable devices engaging the sleeves for vertically adjusting the latter to maintain the enlarged portions of the stems within the operative influence of the magnets.

An electro-magnetic battery comprising dies, stamp heads having stems with enlarged portions, sleeves having nuts for vertically adjusting the sleeves, said sleeves carrying upper magnets, the enlarged portions of the stems co-operating with the said upper magnets, and other lower magnets also having portions of the stems in co-operative relation thereto.

DUMP-BUCKET.—No. 910,253. Lewis Wolfley, Prescott, Arizona.

In a dump bucket, a main body portion, a lower portion having a section fixed with respect to the main body portion and sloping toward the centre axis of the bucket, a hinged section also sloping toward said axis and co-operating with said fixed section, and means for latching said hinged section.

TURBO-PNEUMATIC DRILL.—No. 910,428. John W. Smith, Philadelphia, Pennsylvania.

In a pneumatic drill, a casing, a rotor having turbine buckets therein, speed changing mechanism for said rotor, and a detachable stator provided with channels for re-directing motive fluid against said buckets.

In a pneumatic drill, a casing, a rotor having turbine buckets therein, speed changing mechanism having a friction clutch, an automatic brake for said rotor, and means for impinging the motive fluid against the rotor.

Telephones for Mining Plants.

Nothing thus far devised gives the superintendent of a mining plant a greater feeling of security than a knowledge that he has complete control over all parts of his plant through a telephone system. A reliable telephone system saves time and money and facilitates co-operation between the superintendent and his men. It provides means for notifying the men working in the near and distant portions of a plant of a temporary suspension of the power, of a neces-

Magneto Telephone Set.

sary shut-down of some part of the plant, of an accident to the machinery, of immediate repairs to be made, or of other changes. In small as well as in large mining plants, emergencies affecting both life and property often arise which render a telephone system invaluable.

Telephones for mining operations may be divided into

Telephone Set Open.

two classes: those for use in the buildings above ground, and those for use in the mines. Owing to the moisture and gases present under-ground, the telephone apparatus for such situations must be enclosed in iron-clad cases to prevent corrosion and decay. Otherwise, the apparatus does not materially differ from the telephone equipment employed above-ground in the superintendent's office, and in protected parts of the plant. The accompanying illustrations show exterior and interior views of a Western Electric

Magneto Telephone set, particularly adapted for mining service. The battery-compartment is large enough to hold three standard dry-cells. A writing shelf, mounted below the transmitter, is convenient in making notes of orders received over the wire. Improved 'Blue Bell' dry-cells are recommended for mining telephone work. Competitive tests show them to have a longer life and higher efficiency than other dry-batteries on the market. A special feature of these magneto telephone sets is the location of the main binding-posts inside the cabinet. This prevents trouble from tampering with the connections and accidentally short-circuiting a set at the main terminals. All the binding-posts are fitted with screw connections. The permanent connections are soldered and the terminals attached to flexible leads are provided for the battery. All apparatus in these sets is made in accordance with the standard of the Western Electric Co. of New York.

Publications Received.

Any of the books noticed in these columns are for sale by or can be procured from the MINING AND SCIENTIFIC PRESS.

COMPARATIVE TESTS OF RUN-OF-MINE AND BRIQUETTED COAL ON LOCOMOTIVES. By W. F. M. Goss. Bulletin No. 363, U. S. Geological Survey.

TESTS OF COAL AND BRIQUETS AS FUEL FOR HOUSE-HEATING BOILERS. By D. T. Randall. Bulletin No. 366 of the U. S. Geological Survey.

THE DESIGN OF HIGHWAY BRIDGES. By Milo S. Ketchum. 8vo., pp. 544., Ill., Index. The Engineering News Pub. Co. New York. 1908. Price \$4.

THE GAME FISHES OF BRITISH COLUMBIA. Bulletin No. 25. An admirable series of photographs, with descriptive matter, for those who pursue trout or salmon either for profit or pleasure.

Catalogues Received.

THE HARDINGE CONICAL MILL CO., New York, has recently published a small booklet on the evolution of the conical mill. It also discusses the advantages of the Hardinge conical mill.

THE DEMING CO., Salem, Ohio, has lately published an attractive catalogue of its spray pumps. Included is a folding plate on which is given a spraying calendar and formulas for different remedies. Deming spray pumps may also be used to advantage in whitewashing mills, factories, and the like.

THE AVERY CO., Peoria, Illinois, is distributing its 1909 catalogue describing its well known line of traction engines, threshers, and steam-plows. A noticeable feature of this pamphlet is the excellent illustrations, prominent among which are the two double-page illustrations in natural color, one of the Avery steam-plow outfit and the other of the thresher.

Commercial Paragraphs.

E. M. WADE, of the firm of Wade & Wade, Los Angeles, has established an assay office at Nogales, Arizona.

THE WELLMAN-SEEVER-MORGAN CO., Cleveland, announces that it will be represented in the West by F. H. Bostwick, who will have an office at 611 Ideal Bdg., Denver.

THE BURNITE MACHINERY CO. has succeeded to the business of the Burnite-Leonard Engineering Co., and has established an office and store-room at 17th and Glenarm streets, Denver. Thomas B. Burnite is manager of the new company.

ROBERT W. HUNT & Co. have engaged the services of John Cargill, who will make his headquarters at the firm's New York office, No. 90 West street. He will devote his attention to the examination and report upon railway and other corporate properties.

EDITORIAL.

FROM the annual report of the Institution of Mining and Metallurgy, London, we note with pleasure that Charles J. Alford, Willet G. Miller, and Frank D. Adams have been elected honorary members.

ACCORDING to latest advices, the Alaska-Yukon Exposition is to be ready early in May, most of the principal buildings being now in a condition to receive exhibits. This fair is expected to attract big crowds to Seattle and it ought to be effective in advertising the resources of the North.

THIS is a severe winter in the North. Cold and stormy weather has prevailed on the south-eastern coast, and at Dawson January proved to be the coldest month on record, with an average of 43° below zero. On January 24 the thermometer registered a minimum of 65° below, which is only exceeded by the 68° recorded in January 1901. These figures are given by the official meteorologist.

SOUTH AFRICAN capital in American mining is again indicated by the annual report of the South African Gold Trust, Limited, showing that among this important company's holdings are 48,280 shares of Oroville Dredging and 35,000 shares of Yuba Consolidated; on the other hand, the 27,000 shares of Camp Bird, held in 1905, have evidently been sold.

NEWS from our correspondent in the Tanana region of Alaska indicates that the headwaters of the Kuskokwim river is to be the scene of a stampede this spring. A strike has been made on Tuluk-sak creek, a tributary entering the Kuskokwim at about 100 miles from its mouth. Work done during the summer of 1908 proved encouraging. Good prospects are also reported about 80 miles up the Anvik river.

THE FEBRUARY bulletin of the American Institute of Mining Engineers has for its frontispiece a portrait of James D. Hague, accompanying a biographical notice written by Dr. Raymond. The portrait is a speaking likeness and will touch many a man in the distant places of the earth with a mingled feeling of pleasure to recognize Hague's kindly face and of sorrow that he has crossed the range. Many old memories will be recalled by Dr. Raymond's biographical note, into which, as usual, he has injected so much of himself as to make the article doubly interesting to his friends.

ON THE retirement of Mr. William Gowland from the chair of metallurgy in the Royal School of Mines, it is announced that Mr. W. A.

Carlyle, lately general manager of the Rio Tinto, has been selected as his successor. We felicitate Professor Gowland on the affectionate esteem he has won from his students and the usefulness of the work accomplished by him as a teacher at South Kensington. To Mr. Carlyle we extend congratulations on an appointment both honorable and important, with best wishes for the highest success in the exposition of the metallurgical principles which he is so well qualified to elucidate.

WE NOTE with interest that a bill has been introduced in the Montana legislature embodying a suggestion appearing in these columns last November. Immediately after the presidential election we referred to the loss of the suffrage on the part of those whose business takes them away from home. The Montana bill recognizes that commercial travelers, railroad employees, stockmen, and others are necessarily absent from their voting precinct on election day and allows them to vote by mail. Proper safeguards are provided. There is even less danger of misrepresentation than in making a payment of \$10,000 in the ordinary way by check sent in a letter. We hope the bill will pass.

Steel Prices.

Spectacular depressions in the stocks of a single great corporation which in the nature of things can no more be expected to collapse than can the Government itself, compel attention, and suggest contrivance to achieve a hidden purpose. The wild selling of United States Steel securities during the week appears unwarranted by industrial conditions. It is true that an enormous decline in production has been continuing for more than a year, and it is also true that the production of other metals has been out of balance with the shrinking output of iron and steel. The most conspicuous case in point is that of copper, in which an increase of 8.3 per cent occurred last year over the production for 1907, while during the same period the decrease in iron ore mined and smelted amounted to 36 per cent. The Steel Corporation, from its pre-eminent position as controller of a commodity upon which the complex industries of modern life so vitally depend, should have regulated and strengthened the business activities of the country. Instead of that it has stood as a menace and a deterrent through arbitrarily sustaining prices at a high level, without giving guarantees against change in the schedule for a definite period. It was reported that the independent steel manufacturers prevented action of this kind some months ago, but that is difficult to believe. The independent steel-makers were in too perilous a predicament from the financial depression wilfully to provoke further unsettling of business conditions. It requires no large intelligence to appreciate the impossibility of a normal revival of industry in the face of uncertainty in the price of a necessary element like iron and steel. Unless the price rule steady for a reasonable time manufacturers and dealers cannot accept orders save for immediate delivery. Large business is not done in that way.

The time-factor is vital in enterprises of magnitude, and revival from a financial crisis is not accomplished through hand-to-mouth transactions. The independent steel producers beyond doubt would have welcomed such regulation of prices; manufacturers everywhere were pleading for it; the cry was universal for certainty, for fixedness, even on a higher plane of prices if need be, so that estimates might be made and contracts entered into with security.

What restrained the Steel Corporation from taking so salutary a step can only be surmised. To lower the price would have been a confession anticipating Mr. Carnegie's explosive dictum; to advance it would have stimulated the attacks of those who insisted upon a reduction of the tariff. It is certainly significant that the present bear movement has come at a most opportune moment to intimidate Congress. No reduction in the tariff on steel will be sanctioned by a public repentant after such financial castigation as it has just received. Resistance of the paper storms produced by Wall Street's tampering with the barometer will come only when men learn to trade in the substance rather than the shadow. Whether premeditated or not, the effect of the Steel flurry in deterring Congressional action is inevitable, wherein we see how dissimilar is protection from pampering, and what widely different degrees of avarice they excite.

Geological Hierophants.

"According to the quantitative classification, this rock belongs to monzonose, the sodipotassic subrang of the domalkalic rang of the perfelic order of dosalane. It is, however, near the border between the domalkalic and peralkalic rangs, and a relatively small increase of the alkali percentage would throw it into the subrang ilmenose. It is evident that the larger part of the albite molecules enter into the composition of the perthitic alkali feldspar; if most of them went to the formation of plagioclase crystals, the rock would have a monzonitic habit."

It looks vicious, undoubtedly; you wonder what has happened. At first, the compositor is debited with undisciplined exuberance, but you decide that the frills are too orderly to arise from mere typographical error and you begin to surmise that the supper last night has affected your eye-sight by way of your liver. Something is wrong. Either you are a hopeless idiot or the other fellow. And it is not the other fellow. This is a scientific cryptogram. The sentence serving as a text for these disjointed remarks is taken bodily from page 49 of Professional Paper No. 62, recently issued by the United States Geological Survey. The monograph so designated is devoted to 'The Geology and Ore Deposits of the Coeur d'Alene District, Idaho', and it was prepared by Messrs. F. L. Ransome and F. C. Calkins.

It is obvious that the information contained in the statement above quoted must prove of great value to the citizens of Idaho, and we can imagine our friends at Wardner and Wallace expressing their gratitude forcibly, if inelegantly, for so illuminating a chunk of geologic science. But, coming to plain talk, is it

not an impertinence to inflict the average citizen with such sesquipedalian verbal gymnastics? The reports of the Survey are intended primarily for the use of the people in the mining district serving as the subject for investigation, and after them for people interested in mining geology in the United States, and finally for scientific men. We confess that, belonging to two of these classes and in cordial sympathy with the third, we found ourselves first astonished at the terminology of the paragraph quoted and then we deemed ourselves flouted by the authors, for it is unpleasant to be made to feel like an ignoramus. Having heard of a new classification of rocks that had been invented by Messrs. Cross, Penfield, Washington, and Iddings, we guessed the clue, that is, we knew where to get the code-book. Thereupon we went to a University library, and after rummaging on three floors of that museum of learning we finally found Volume X of the *Journal of Geology*, wherein the key to these verbal monkey-shines is hidden. A group of four petrographers occupied the spare moments, devoted by lesser men to harmless dissipation, in concocting a quantitative chemical classification of rocks, and for this purpose they divided the rock-forming minerals into two groups, namely, the silicious, alkali-, and calci-aluminous, which they labeled *salic*, and the ferro-magnesian, which was labeled *femic*, much in the same way as the Coniagas mine at Cobalt was christened from the first two letters of the chemical symbols that stand for the elements cobalt, nickel, silver, and arsenic. The subdivisions, named *rangs*, are founded on the chemical character of the bases in the minerals of the preponderant group in each case; the lowest division is called a *grad*, and for finer work *subrangs*, *subgrads*, and so forth, were invented. If a factor is extremely abundant the prefix *per* is used; if only dominant, then the prefix *do* or *dom*—at this stage the Irish pronunciation of a more familiar term will be readily on the reader's lips. But he must not be so easily discouraged. 'Fel' is a mnemonic of feldspar, so that *felic* means feldspathic, and *perfelic* means particularly, deliciously, and astonishingly feldspathic—do you see the game now? Terminations *-ane* and *-one* indicate a class and a sub-class, as *-ase* and *-ose* indicate a *rang* and a *subrang*. We are informed (and this is consoling) that "these terminations were selected after trial of many that were suggested." Cheer up, you don't know what you escaped! Of course, we are aware that from the standpoint of the petrographer the quantitative chemical classification of the petrographical trust affords a neat and satisfactory system of description, but the reports of the Survey are not intended primarily for petrographers, but for laymen, that is, for the general public interested in mining, or, to put it even plainer, for the taxpayers who pay for the preparation of the reports. Anyway, is it not all plain as a pikestaff; you ask what mozonose is: well, have not Messrs. Ransome and Calkins told you explicitly and in the abracadabra of speech that it is a "subrang of the domalkalic rang of the perfelic order of dosalane," and if you are still in doubt, cable to Bedford McNeill for his codebook.

The Institution of Mining and Metallurgy.

The eighteenth annual report of the Institution of Mining and Metallurgy indicates the continued growth and prosperity of this society of engineers. While the membership is not big, it is representative of the best elements in the profession, not only in England but wherever British capital is invested in mining. In consequence, a large sprinkling of Americans is included, giving the Institution an international scope. At present 1800 names appear on the list of members and associates, indicating an increase of 1298 in ten years. But mere numbers do not constitute strength, for that we must look to the quality of the transactions of the society and to its tonic influence upon the profession. In these respects the Institution has done well. Although in some subjects, such as economic geology, the American Institute is still ahead, it is gratifying to note an increase of contributions on ore deposition, while in contributions concerning cyanidation, sampling of mines, and underground practice, the Institution has done splendidly. On the whole, however, the most important work accomplished has been the standardization of terms and the pronouncements on matters pertaining to professional behavior. The service done in these directions has been invaluable, and the general acceptance of the dicta issued from Salisbury House bears testimony to the respect which the society has won throughout the English-speaking world. This result is due, in large part, to the thoroughly representative character of the Council of the Institution; a technical society must be ruled either by a committee reflecting the character of its membership, or it must be managed by one man of strong personality and ability. Both methods possess advantages, but as men of first-rate ability willing to devote themselves to the service of technical societies are rare, it is well that they should be managed by a select oligarchy rather than a benevolent despot. A perfectly representative type of government, in societies as in national affairs, is desirable, but unfortunately, in societies as in nations, representative government in its perfect form remains an unattainable ideal. To these general statements we need only add that the group of men that controls the affairs of the Institution not only represents the best elements in the profession but, as far as we know, those men have used their power in the best interests of that profession. Of course, a membership of 1800 is small in proportion to the multitudinous mining activities of the British empire, and the Institution, as regards numbers, has not yet grown commensurately with the vast industry of metal-mining having headquarters in England. Through evolution by careful selection, a successful effort has been made to bar the irresponsible among those engaged in the conduct of mining affairs. Now that the Institution has won a deservedly commanding position, we hope all who are qualified will join, so that in numbers as well as in character this society may be fully justified in being considered the representative association of those taking an honorable part in the manifold technical operations connected with mining.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

FRANK H. PROBERT is at Butte.

FRANCIS L. BOSQUI is at Tonopah.

J. H. CURLE is on his way to Kashmir.

NEWTON B. KNOX is on his way to Korea.

HAROLD RICKARD has moved to El Paso, Texas.

W. J. LORING is expected in London from Burma.

ERNEST WILLIAMS has left London for Kalgoorlie.

ROBERT A. KINZIE, of the Alaska Treadwell, is here.

JOHN A. RICE, of El Paso, is now in Sinaloa, Mexico.

E. A. MANNHEIM is on his way from London to Brazil.

JOHN H. HUGHES, of Fairbanks, Alaska, is in London.

A. R. WEIGALL has returned to Australia from Korea.

E. J. FRANZ has returned to Plumas county, California.

A. G. KIRBY, of Reno, Nevada, was recently at New York.

EDWIN H. MESSITER was in San Francisco on his way to Oroville.

HIRAM W. HIXON has returned to Canada, after a visit to London.

F. F. SHARPLESS passed through San Francisco on his way to Butte.

P. GEORGE GOW has returned to San Francisco from a holiday in Europe.

PERCY E. BARBOUR is designing a mill at Minas Nuevas, in Sonora, Mexico.

JAMES M. HOLMAN, of Camborne, Cornwall, is spending a holiday in Egypt.

HUGH C. WATSON has gone from Goldfield to Mapimi, in Durango, Mexico.

WALTER W. BRADLEY has returned to Berkeley, Cal., from Ventanas, Mexico.

L. K. FLETCHER has obtained a position at the Karma mine, near Mojave, California.

ALLEN C. REDDING, of San Francisco, is now examining mines near Barstow, California.

WAGER BRADFORD has been appointed manager of the Robinson mine, at Johannesburg.

GELASIO CAETANI has left Treadwell for the Bunker Hill & Sullivan mine, at Kellogg, Idaho.

DAVID COLE is assistant manager to the Cananea Consolidated Copper Co. in Sonora, Mexico.

W. C. RALSTON has been elected a vice-president of the American Institute of Mining Engineers.

GEORGE E. WEBBER, general manager for the Rand Mines, Ltd., is about to leave the Transvaal, returning to California.

F. H. HATCH has been engaged by the Government of Natal to report on the mining possibilities of Natal and Zululand.

E. S. PETTIS has returned from the Soledad mine, Mojave, and is now with the Butters Patent Vacuum Filter Co., San Francisco.

WALTER FITCH, until lately superintendent of the Calumet & Hecla, has taken charge of the Little Chief mine, at Eureka, Utah.

E. E. CARPENTER has left the Belmont mill, at Millers, Nev., and has taken charge for the Just Mining & Extraction Co., at Goldfield.

HENRY M. ADKINSON has returned to Denver from Telluride, Colorado, where he has been inspecting the properties under his management.

H. VINCENT WALLACE and M. W. SUMMERHAYES, of Nogales, Arizona, have opened a branch office at Patagonia, with C. W. MORGAN in charge.

General Mining News.

ARIZONA.

COCHISE COUNTY.

At a depth of 120 ft. the Centurion Mining Co. has found a crevice in the rock at the bottom of the shaft through which there is so strong a current of air that the miners are able to descend the shaft within five minutes after firing a round of shots. The company has also found ore worth over \$20 per ton.

GILA COUNTY.

In the Eureka shaft of the Arizona Commercial Copper Co. a cross-cut from the 700-ft. station to the Black Hawk lode has run into ore averaging 6% copper. It will be drifted on both ways. The raise from the 560-ft. intermediate level has been holed through and a connection made with the fifth level. A winze has been started, from the bottom of which a drift will be driven west to connect with the Eureka shaft, about 650 ft. distant.

PINAL COUNTY.

The diamond-drill holes at the mines of the Ray Consolidated Copper Co. indicate the presence of about 15,000,000 tons of ore averaging 2.5% copper. Immediately adjoining the Ray Consolidated property, and in the same porphyry belt, is a series of claims in which about 2,000,000 tons of ore have been blocked out. A new company has been formed, known as the Ray Central Copper Co., to acquire these claims from the Kelvin-Calumet Company.

YAVAPAI COUNTY.

(Special Correspondence).—The adit belonging to the Hull Copper Co. has now been completed by reaching the 1888 claim with a length of 4680 ft. Work was started several years ago by Ralph Dillon, in memory of whom the adit will be locally called the 'Dillon Tunnel.' In driving it several bodies of good ore have been found, some of which now lies on the dump ready for the company's small smelter to treat.—The Verde Grande Co. has now sunk its main shaft 838 ft., and has been cross-cutting at the 800-ft. level. The east drift has advanced about 500 ft. in a vein that looks promising.—The 10-stamp mill and cyanide plant of the Etta mine in the Cherry creek district has been completed, and will be started early in March. H. H. Keays is superintendent.

Prescott, February 18.

This week at Prescott, before Judge Sloan, the Blue Ridge v. Tom Reed mining case was further threshed out. The defendant company moved to dissolve the injunction recently issued by the Court Commissioner and the motion prevailed. T. E. McClelland, of Kingman, and ex-Governor Charles S. Thomas, of Colorado, appeared for the Blue Ridge people, and Norris & Ross for defendants. Upon amendment of complaint along the lines laid down by the Court another clash will probably take place.

CALIFORNIA.

NEVADA COUNTY.

A complete survey of the 500 and 700 ft. levels of the Idaho-Maryland mine has been made, and an ore-shoot has been discovered which Bray Wilkins, the manager, says is a new orebody, with well defined walls, lying parallel to the old vein.

SHASTA COUNTY.

The annual report of the First National Copper shows the operation of the smelter during a portion of three months. In 53 days there were treated about 26,000 tons of ore, most of which came from Balaklala. The average copper content of the ore was 2.7%, and the total cost of production is indicated at about 10c. per lb., which is quite satisfactory for preliminary operations of a smelting plant.

SISKIYOU COUNTY.

Placer mining is booming along the Salmon river in consequence of the abundance of water. The Johnson flume

below Sawyer's Bar is finished, and nearly ready for operation; the Bonally Co. have 35 men at work completing their ditch line; and the Bennett Co. are now hydraulicking five placer claims at the Forks of the Salmon.

TUOLUMNE COUNTY.

One hundred men are working on what is reported to be good pay-ore in the mines of the United Mines Corporation. The properties include the Grizzly, New Albany, Lady Washington, and Dead Horse. On the 300-ft. level of the New Albany a good strike of ore has been made; the corporation is going to operate another of the mines near Carter's, the Old Dead Horse, which in former times was developed down to the 1500-ft. level.

YUBA COUNTY.

The lawsuit over the Solano Wonder gold mine at Brownsville has been decided at Marysville in favor of J. C. Campbell and his wife. It appears that J. Lang and B. F. Ream took out 60 sacks of ore from a piece of ground which they believed to be Government land, and subject to location. Ascertaining that the find was made close to their old abandoned shaft, the Campbells had the ground surveyed and found that the Solano Wonder was on their own patented land, and have now obtained judgment for the sacks of ore extracted, together with \$1000 damages.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Philadelphia M. & T. Co. has been organized with a capital stock of \$1,000,000 by H. E. Woodward, J. V. Wood, and H. W. Robinson, and the principal office will be maintained in Denver. A group of claims on Kelso Mtn. has been purchased from J. T. Hamill and work has already been put under way. The adit 500 ft. long is to be advanced at least 1000 ft. farther to cut the veins at depth. A plant of machinery is to be installed in the spring.—G. Laughlin, of Chicago, representing a syndicate of Eastern capitalists has taken over the Magnet group of mines on Saxon Mtn. The bond calls for \$80,000, and it is understood that a cash payment of \$20,000 has already been made. Laughlin has also entered into negotiations for the rental of the Doric adit, and the papers will be signed as soon as the stockholders residing in London have been communicated with. Working capital has been subscribed and it is expected that actual operations will be under way within 30 days. The Magnet mine was never worked to a depth exceeding 600 ft., and where the vein was intersected through the Doric adit a body of smelting ore was exposed that is from 1 to 4 ft. wide. A stope was carried for 175 ft. and the lowest returns ever received in settlement on ore were \$29 per ton in gold, silver, and copper, while returns of \$174 per ton have been realized on the first-class product.—The McClellan Mtn. M. & M. Co. is working in a diligent manner upon the Vesper group of claims in East Argentine. The adit has been extended 725 ft. and during the last week the Vesper vein was intersected. Scattered mineral is showing, and drifting has been begun under way to prove the ground. This company is being financed by Minneapolis capitalists and enough funds have been provided for development. The work is being performed under contract by H. Davenport.—William Rogers, of the Santiago, has been adding to the working force during the last week. Much development has been planned for the fourth and fifth levels and shipments of both smelting and concentrating ore are to be made to the Santiago mill in Georgetown. As soon as the weather permits work will be started on the construction of the new aerial tramway which will run from the fifth level of the mine to the mill in Georgetown. The tram will be about three miles long.

Georgetown, February 20.

GILPIN COUNTY.

Sinking operations are being carried on at the Pooch shaft of the Gilpin Boulder Consolidated Mines Co. in Lake gulch and a depth of 40 ft. has been reached. The bottom of the shaft shows a 24-in. vein of which there is a small streak.

the remainder being free-milling ore. At present the entire vein matter is being sent to the stamp-mill. E. H. Crabtree is superintendent.—A shipment of several tons of smelting ore from the Baxter mine on Quartz hill has brought returns of \$85 per ton. The property is owned by McFarlane Bros., and has been idle for a number of years, but was recently started up under a lease to Moe & Co.

GUNNISON COUNTY.

A. E. Reynolds is enthusiastic about the Gold Links mine, near Ohio City. He has about 50 men employed in the mine and mill and has just installed a 12-drill compressor to assist the development at the end of the 3300-ft. adit.

LAKE COUNTY.

A diamond-drill connection has been made between the No. 1 and 3 shafts of the Ibex property, through which the water of the No. 3 will drain into the other shaft, and thence out through Yak 'tunnel' into California gulch.—Many of the Leadville mines are in a serious predicament on account of lack of fuel, due to railroads being stopped by snowdrifts. Those mines served by electricity have been in no way hampered, and this has caused several managers to consider protecting the steady operation of their properties by such an installation.

SAN MIGUEL COUNTY.

Gustav H. Schwab, vice-president of the North German Lloyd, has asked the United States District Court of Telluride for an injunction against the Smuggler-Union, the Tomboy, and the Liberty Bell mines to restrain them from emptying their tailing in the San Miguel river and thereby ruining his placer grounds. Schwab's claim is that the tailing from the defendant mines turn the San Miguel into liquid mud. So muddy is the water that it is impossible to use it in placer operations. The tailing also covers a great deal of his ground with deep sediment. The farmers are also lending their support, as the water is rendered bad for domestic purposes.

TELLER COUNTY.

In the first fourteen days of February 170 ft. have been driven in the Roosevelt Deep Drainage tunnel. The official measurement of the total length on February 9, shows 3625 ft. as having been accomplished, indicating 302 ft. as the average length driven per month.—A five years' lease has been secured by M. B. Burke for the Henry Adney Gold Mining Co. of the properties of the Black Belle Gold Mining Co. on Beacon hill. The Black Belle claim is at present under a lease expiring on May 1. Under the lease conditions the shaft must be sunk an additional 200 ft. from the present depth of 400 ft. It is Burke's intention to install an electrically driven compressor and to develop the property with machine drills.—A new vein on the property of the Gold Dollar Consolidated Co. has been opened up by C. G. Jackson, of the Union Leasing Co., by a cross-cut east from the 400-ft. level of the Mable M. shaft. The new orebody measures 8 ft. between walls and mine samples assay from \$10 to \$38 per ton.—An Illinois company, represented by Spratt Bros., operating at the head of Barnard creek, about 1½ miles northwest of the town of Gillett, is reported to have opened up 'pay' ore on its property.—An electric hoist is being installed by the La Bella Investment Co. on its lease on the Pueblo claim of the Free Coinage Gold Mining Co., east of the town of Altman. A new shaft-house is also under construction and the general manager, W. Wilson, will commence sinking an abandoned shaft on the Pueblo, now about 60 ft. deep, in search of an ore-shoot in that immediate neighborhood.

IDAHO.

LATAH COUNTY.

The present workings of the Inland Copper Co.'s property, 8 miles east of Troy, are down 160 ft. and a 20-ft. vein has been tapped; but the greater part is oxidized with the copper leached out, leaving a porous quartz with iron sulphides and some ribbons of rich copper ore. The company has done 1000 ft. of development work and hopes to find better copper ore in depth.

NEZ PERCE COUNTY.

Fifteen mineral claims carrying veins of asbestos were located in June 1908, the claims being staked off and appropriated in compliance with the provisions of the laws of the United States. It now appears that the lands were not subject to entry, but are lands belonging exclusively to the State of Idaho. The State Board of Land Commissioners of Idaho is now being besieged by applicants desiring leases of those lands which are believed to contain minerals. The applicants will probably obtain them on certain conditions of paying royalties.—The Ozark Mining & Milling Co. has just completed plans for a 100-ton mill and is driving an adit on the Wild Rose claim to cut the vein at a depth of 500 ft., the greatest depth ever attained in the Pierce district. The adit will be approximately 1200 ft. long, of which 775 ft. have already been done. The company has been engaged in development work for the last two years, during which time \$70,000 have been spent.

SHOSHONE COUNTY.

(Special Correspondence).—The principal feature of interest during the past week has been the suit of David Hyman, of New York, against the Frisco Mining Co., in which a default has been entered in the District Court. The suit was for the purpose of foreclosing a mortgage of \$150,000 on the mine, mill, machinery, and claims of the company. The property will now be sold at the sheriff's sale, and it is regarded as certain that Hyman will be the buyer. The mine and mill used to give employment to about 400 men when working at full capacity.—A financial statement has been issued by the Pittsburg Lead Mining Co., covering the period from January 1907 to September 1, 1908. According to this the receipts of the company during that time amounted to \$199,333, of which about \$180,000 was from the sale of ore. The expense of exploration and development came to about \$87,000 and operating the mill cost about \$10,000. An arrangement has been made by which the stockholders will advance money to the company at the rate of 5c. per share.—The new offices of the Bunker Hill & Sullivan Mining Co. have practically been completed, and it is expected that the company will take possession during the coming week. It is believed that the completion of these offices makes the B. H. & S. the best equipped company in this part of the country.—Two 2-drill air-compressors have been installed on the property of the Coeur d'Alene Consolidated Co. The power is furnished by a flume over a mile long. Contracts for 300 ft. of development work have been let by the management, and it is hoped that this will be enough to reach two veins which traverse the property.—The United States Deputy Mineral Surveyors, who have been in convention in Wallace for the past few days, have formed themselves into an association to be known as the 'Association of Engineers of North Idaho.' The organization is the result of a suggestion made by Darwin A. Utter, Surveyor General for Idaho. The officers chosen are as follows: president, G. Scott Anderson; vice-president, R. S. Merriam; secretary, A. E. Robinson. The executive board consists of C. F. O. Merriam, A. E. Robinson, and Frederick V. Phinney. It is the intention to hold regular annual and monthly meetings at which all matters connected with surveying of mineral lands, etc., will come up for discussion.

Wallace, February 18.

Harvey M. Ross, one of the owners of the Sidney group of claims on Pine creek, adjoining the Nabob mine, reports that the vein has been struck in the adit now being run in the Sidney. This vein was first seen in the centre of the creek, but water prevented operating there, and a cross-cut was started higher up. When first uncovered there were showing three feet of good ore carrying galena and zinc.

MICHIGAN.

It is rumored here that a deal is under way to consolidate the Ahmeek and Seneca mines, making a company with 100,000 shares. Ahmeek is understood to be financing exploratory work now under way at Seneca.—Record progress is there being made in shaft sinking and cross-cutting at the Seneca mine. The cross-cut is now in about 43 ft.,

and driving is being done at a rate that should disclose the Kearsarge lode within a week.—Allouez has encountered the Kearsarge lode in the cross-cut on the 14th level of the No. 2 shaft. The first round of blasts showed excellent copper ground. The company will continue cross-cutting until the foot-wall is reached, when sinking on the lode will be resumed. Arrangements are now being made to turn the shaft to conform to the dip of the lode.—Victoria reports a decided improvement in the bottom of the mine, where drifts are working into ground exceptionally rich in mass copper.—The coming spring will undoubtedly see active work started in sinking Mohawk's No. 6 shaft, between No. 5 and the Ahmeek boundary. The shareholding public has greater faith than ever in the Mohawk mine's future prospects.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—In the American Davey mine at Prosperity a second steam-shovel is to be installed at once. The first steam-shovel in the district was used here and proved a success. The shovel cannot be used in all these mines, as it requires ground where there is no timbering or where very few pillars are left, and where there is sufficient room for a large shovel to work. The new machine will embody several improvements on the former model, as the company has been making a careful study of the machine to see wherein it could be improved.—An interesting experiment is being conducted in Poor Man's

Florence Mill, Goldfield.

gulch near Joplin by the Poverty Mining Co. A large concentrating plant handling 200 tons has been erected for treating the old dumps of the mines worked 14 years ago. It is thought that a considerable percentage of zinc-blende can be recovered from these sources, as the inadequate facilities of those days did not permit of saving low-grade ore.—Another drill strike in the Midway camp near Joplin is exceptionally rich. In the area of one acre several drill-holes have been sunk showing a run of ore beginning at the 50-ft. mark. The first 20 ft. is galena, while a 9-ft. bed of zinc-blende occurs below this. The strike is near the old Cardinal mill on the Conqueror lease, once one of the bonanzas.

Joplin, February 18.

MONTANA.

MADISON COUNTY.

The American Goldfields Co. has been organized in Spokane with a capitalization of \$1,000,000, to develop a group of claims 12 miles from Alder creek. The officers of the company are: N. Valentine, Harry J. Gibbon, F. C. Hickok, and Frank C. Lavigne. The property has been operated more than five years, but owing to the shortness of the season the owners were unable to realize profits. The equipment, which represents an expenditure of \$18,000, consists of ditches, flumes, pipelines, and hydraulic machinery. The

company will construct a reservoir and dam for the storage of water, in the hope that this will lengthen the season and permit operation at least nine months of the year. The company owns four miles of bottom lands which yield 40 cents per yard.

SILVER BOW COUNTY.

Charles Cote is doing a good business at Butte by collecting discarded tin cans all over the State and selling them as material for the copper precipitation plants. To prevent unwieldy bulk, the cans are compressed in a hay-baler, and make very suitable material for the precipitation process.

In the course of his testimony before Judge Hunt in the Federal Court, E. P. Mathewson made the statement that 90% of all the ore received at Washoe is concentrating ore and only 10% goes direct to the furnaces. The ore yields in arsenic all the way from a mere trace to 2½%, and an average amount of two tons is recovered daily. He further said that every method of eliminating arsenic from the smoke had been investigated, and that the system now in use is about as perfect as can be made. At Great Falls a new method is being tried, and if it proves more successful than the process now in use at Washoe, it will be substituted at the latter plant, although the change would cost the company over \$2,000,000.—The shaft of the Diamond mine of Anaconda has reached a depth of 2400 ft. and has passed through ore near the bottom. Sinking is still going on.—A test run has been made with the East Butte Co.'s new concentrator, with results that demonstrate the feasibility of a principle that may revolutionize concentration. The method is being kept a secret, but the system is said to be automatic, very economical and simple, and will concentrate the lowest grade of ore.—A cross-cut on the 2000-ft. level of Parrot has just entered the vein at a distance of 500 ft. from the shaft and the heading has reached ore. The vein on the 1900-ft. level though wide is disappointing in value.

NEVADA.

CHURCHILL COUNTY.

The installation of the new 15-hp. Fairbanks-Morse hoist has been completed at the Mary H. claim of the Jessup Mines Co.'s estate, where a 2-compartment shaft is being sunk to the 200-ft. level.

ESMERALDA COUNTY.

The officials of the Goldfield Consolidated Co. have unearthed a complete counterfeiting plant equipped with furnace, dies, a press for stamping out coins, engravers' tools, etc., for forging time checks, whereby the company is supposed to have lost some thousands of dollars.—One hundred men are now on the pay-roll of the Florence Goldfield Mining Co., and more are being added as fast as the enlarging of underground operations will justify. It is probable that by the first of March, there will be fully 80 men in the underground workings, in addition to the mill and other employees on the surface. Thomas G. Lockhart says there are only three sets of lessees working on the Florence, and when their time is up he does not expect to do any further leasing.—The *Goldfield News* estimates that there are 1536 men employed in the mines and mills of the district, obtaining an average monthly pay of about \$184,000, of which the Goldfield Consolidated Co. alone contributes \$68,000 per month.—It is rumored that an immense body of ore has been opened on the 600-ft. level of the Combination Fraction workings, and it is believed to be the continuation of the Loftus, Davis & Sweeney orebody which made some remarkable history in the early days. Eight power drills are being used in development, and an average of about 75 tons of ore per day is being treated at the mill of the Nevada Goldfield Reduction Co. Leadville is the name of a new camp some 10 miles southwest of Goldfield, where R. D. Edwards and about 17 men are working on ore which carries silver and lead.

ESMERALDA COUNTY.

R. B. Reed, of New York, has just in the past week further developed the

plant at Gold Centre. The water-supply at that point is found to be excellent, and as soon as Respass finds that 300 tons of ore can be obtained daily, he will be prepared to set work under way for a mill of about that capacity. With Respass is associated W. D. Lawton, who will have charge of the construction work.—The Homestake King mine shipped \$16,000 in bullion as the result of the January run of the mill. Slightly more than 2000 tons of ore were treated during the month, as compared with 1500 tons, resulting in \$12,000, for December. The cyanide plant is now in efficient working order. S. B. Tyler assumed charge of the Homestake mine and mill on February 10.—The Tonopah Mining Co. sent 3050 tons, the Belmont 950 tons, the Montana-Tonopah 779 tons, the Midway 100 tons, the Mac-Namara 250 tons, West End 200 tons, and Jim Butler 300 tons to the mills, making the total shipments for the week 5629 tons. With shipping ore valued at \$60 per ton and milling ore at \$25 per ton, the total estimated values of this output is \$140,000.—The Tonopah Mining Co. has recorded

Nevada, Showing the New County.

an advance in development work of 506 ft. for the week, of which 361 ft. were done in the Mizpah. A drill-hole is being put down from the 740-ft. level of the Silver Top, and has now reached a point 437 ft. below that level. The Red Plume shaft is now about 500 ft. deep, and sinking is being continued in order to reach a good body of quartz discovered in one of the diamond-drill holes.—At the Belmont work has been done blocking out the orebody on the 1100-ft. level, and up to date its total extent has not been fully ascertained, although several raises have been put up connecting with the 1000-ft. level. What new ore has been discovered in the general development of the mine has proved to be of a most satisfactory nature. The Round Mountain Hydraulic Mining Co. is working three shifts on its Blue Jacket placer claim. About a month ago it started a 2-in. giant, and has kept it going night and day ever since. Superintendent Benkie is in charge, and will have another giant at work before long. The stream is directed upon a bank from 3½ to 6 ft. deep which shows gold almost through its entire depth.

NEW MEXICO.

GRANT COUNTY.

About a year ago H. W. Baylor and H. J. Bowles, two cattlemen of Uvalde, Texas, grubstaked W. Q. McKinney to go to Sylvanite, where he located the Pearl and Monte Christo, two adjoining claims, in the southeastern part of the district. The vein has been opened up within the last month, and a number of splendid pieces of 'specimen' ore have been uncovered. The vein is of granulated quartz, 30 in. wide, impregnated with free gold, and on the foot-wall side is decomposed slate which also gives good assays of gold.

OREGON.

MALHEUR COUNTY.

A well had been driven 2210 ft. at Ontario, when suddenly a terrific explosion of mud, water, and pebbles took place from the hole, followed by a stream of gas which is now escaping with great violence. Until the necessary tools for capping can be obtained this will all be wasted. The discovery of gas has much elated the people of Ontario, for it is expected that oil will soon follow after.

UTAH.

SUMMIT COUNTY.

A snow block on the 'high line' caused a suspension of operations at the Daly West mine and mill, several shifts being lost on account of the lack of coal. The men at the loading station soon cleared the engines from snow, and opened traffic. The aerial tram at the Silver-King works well in any kind of weather, and it was not necessary to close down at that property. The road to the Daly Judge has also been kept open, and work has been continued there as usual.

WASHINGTON.

FERRY COUNTY.

Thirty men are being employed at the Napoleon mine, situated about 8 miles southeast of Orient. It belongs to the British Columbia Copper Co., and, containing an excess of lime and iron, is useful for the Greenwood smelter as a flux for the other ores received. The shipments now are approximately 150 tons per day, sent from the mine to the railroad by an aerial tramway.—The New Republic Mining Co. has shipped 3 carloads of ore, and has increased its force to 37 men, many of whom are carpenters engaged in erecting the new machinery.—The Mars Hill Mining Co., operating near Rockcut, recently struck a fine body of galena about 800 ft. along the adit of the Jennie mine. The shoot is 8 ft. wide and is associated with chalcopryite which carries gold.—The Kettle River Mining Co. is increasing its equipment with a boiler, hoist, and sinking-pump. At a depth of 50 ft. the shaft has come upon a shoot of chalcopryite and silver-lead ore assaying \$125 per ton. The mine is close to the Spokane Falls & Northern railway, and has E. L. Allen as superintendent.

STEVENS COUNTY.

The McKinley Mining Co., now developing the Dewey claim, has been cutting through a vein for 26 ft., but has not yet reached the hanging wall. Mr. Ekstrom, the president, has been at the mine during the past four weeks.—The Verde Antique marble quarry, at Valley, and the Columbia River Marble Co.'s quarry, near Bossburg, are reported to have passed into the hands of Allan Haynes, an Eastern capitalist, and a new company will be organized to operate these properties in the spring.

SPOKANE COUNTY.

The Idaho-Knickerbocker Mines Co. has been incorporated in Spokane, with a capitalization of \$1,500,000, by W. H. Winfred and J. M. McCroskey, to take over the Charles Dickens property, in the Coeur d'Alene, which was acquired by A. D. Gritman of Spokane at a sheriff's sale some time ago. It was given out that 55 shareholders in the Charles Dickens Co. have subscribed two-thirds of the amount, while 250,000 shares were taken up by stockholders in the new company. The first named have until December 3, 1909,

to redeem the property, upon which thousands of dollars have been expended in development work.

AUSTRALASIA.

The director of the Government Geological Survey states that the discovery of a coal seam at Powlett river is the greatest mineral discovery made in Victoria for 25 years, and will ultimately make Victoria independent of the other States in regard to coal. The quantity of coal available in the new field may be computed, according to the same authority, with the greatest safety at from 10 to 20 million tons.—The Waihi Gold Mining Co. of New Zealand is substituting gas for steam as motive power, to a great extent. At the Waikino mill five 200-hp. Crossley gas engines, together with five others aggregating 175 hp., have been installed, leaving a 520-hp. steam-driven engine to drive the 200-stamp Victoria mill.

CANADA.

BRITISH COLUMBIA.

The mild weather of the past few days has enabled operations to be resumed on mining properties near Kamloops. At the Iron Mask there is a good force of men, while on various other claims clearing work is being done. H. Beckman, owner of the Copper King and Kimberly, has engaged a force of men at the latter property to sink a shaft, while at Copper King the regular staff of eight men is retained.—A shipment of 500 sacks of ore from the Early Bird mine, on Moresby island, to the Tacoma smelter gave returns of over \$60 per ton, while another from the Cornell mine to the Tyee smelter netted over \$20 per ton after paying all freight and smelting charges.—James McMartin, president of the La Rose Consolidated Mining Co. of Cobalt, has taken bonds on the Kootenay Belle and Mother Lode properties in the Sheep Creek camp, in the Boundary district, formerly owned by J. L. Warner, F. M. Black, and F. E. Morrison. The deal was closed after an examination of the property by William Watson, a consulting engineer. The Kootenay Belle adjoins the Queen mine and is almost opposite the Mother Lode. The two groups can be worked together. During the last months in which these mines have been operated, the ore from the Kootenay Belle has been milled, and the high-grade ore from the Mother Lode has been shipped to the smelter for treatment.—The accumulation of ore at the Trail smelter has now been got rid of, and various mines have been sending increased shipments. Developments at the Idaho, Iron Mask, War Eagle, and Centre Star mines continue with satisfactory results. The latter shipped 3000 tons of ore last week. In the Le Roi exploration is being made on the 1750-ft. level for the ore-shoot which is now being developed on the 1650-ft., and W. A. Carlyle, the consulting engineer for the company, is examining the mine to decide on the best method of operation.—Seattle and Boston capitalists are backing a scheme to build a large hydraulic plant on Ruby creek, in the Atlin district, this year.—A new coal mine is being opened at South Wellington, near Nanaimo.—Recent development of free-milling gold claims in the vicinity of Gold Harbor, on the west coast of Moresby island, in the Queen Charlotte group, has proved so satisfactory that the Nuba and Early Bird mining companies will jointly install a 20-stamp mill there early in April. The order for the plant has been placed in Germany.—Recent arrivals from the islands brought news that an English syndicate promoted by a Seattle man is busy diamond-drilling its coal claims on Graham island. Engineers, in charge of J. Kelley, have completed the survey for a proposed 15-mile railway from the coal basin to Charlotte City on the Skidgate.

D. A. Matheson, of the Yukon Basin Dredging Co., has closed a deal for a dredge costing \$70,000, to be shipped North in a few weeks. At present this dredge is lying on the wharf at Vancouver, having been brought from Scotland by Richard Liepman some time ago.

MEXICO.

C. C. Brayton, who for the past year has been in charge of the Santa Francisca mine in Asientos, has gone to

Guanajuato, where he will be connected with the Guanajuato Development Co., which is now under the charge of Cortlandt E. Palmer. Thomas M. Hamilton has succeeded Brayton in charge of the Santa Francisca at Asientos; he was formerly with the Braden Copper Co. of Chile.—The famous Dos Bocas oil-well, which for months shot a column of flame and smoke into the air for hundreds of feet, has been converted into a geyser, and boiling waters are being hurled up at the rate of 25,000 gal. per day, together with a quantity of volcanic stone.—The mines of the Chatterton Mining Co. in the Tapalpa district of Jalisco have been sold to William H. Baldwin, of Delavan, Illinois. The consideration named is \$200,000. The Virginia and San Antonio mines are the principal properties of the Chatterton group. There is a 10-stamp mill and concentrating plant at the mines.—The J. J. & S. S. mine (otherwise known as El Tigre), in the Tepic region, now has a shaft down 190 ft. on the vein, and when 10 ft. farther progress has been made drifts will be run in both directions. Samples taken from the present bottom of the shaft assay \$66 per ton. This promising mine is owned by S. M. Waterman, J. D. Wedgwood, S. H. James, and Clare, conjointly.—The El Oro Mining & Railway Co. is sinking a new shaft on the slope of Somera Mtn., behind the assistant manager's house, to connect with the workings on the 1000-ft. level, now operated through the Somera shaft. Developments in the neighborhood of the San Patricio shaft have been favorable, and the general aspect of the property has prompted Frank Jenkins, the mine superintendent, to say that the old mine is still good for 15 years.—The Mexico mine of El Oro has closed down its mining operations for a month or six weeks while the shaft is being re-timbered; but the 40-stamp mill is kept running on low-grade ore from the dump. The value of the monthly output will be considerably reduced.

An American company with headquarters at Guadalajara has recently applied to the Mexican Government for a concession to construct a railway direct from Aguascalientes to Guadalajara, a distance of about 300 kilometres. The new company does not ask for subsidy from the Government, but that the road be exempted from taxes for a period of 80 years, and that no other railway be permitted to construct a parallel line. The name of the company is the Soledad Development Co., the general manager of which is David B. Russell.—Work is progressing satisfactorily in the Llanos de Oro Consolidated Mining Co.'s mines. This is a consolidation of the Reina de Oro Mining Co. at El Tiro, Sonora Quartz Mines Development Co. at La Yaqui, and the mill at Llanos de Oro. An aerial tramway is being built between the mine and the mill, which at present is running 10 stamps. Developments in the mine have been made to a depth of 700 ft., and for a distance of 1800 ft. along the vein.

W. H. Ellis, of New York City, has taken over extensive properties in the Taviche district, on which a \$2,000,000 company is being organized for development purposes.—Expert geologists are now making examination of the new coalfields of the Tlaxiaco district. The work to date has established the extent and quality of the seams.—Kirby Thomas, of Mexico City, has made a sample shipment of Oaxaca mica to the United States. The quality of Oaxaca mica compares favorably with the North Carolina or Canada product.—A. M. Brooks has taken charge of the San José de Gracia mill of the Mexico Mines Development Co., in the Sierra Juarez camp.—Huntington Adams has taken charge of the properties of the Natividad mine, succeeding Porfirio Torres, who has been the managing director for some time. L. C. Howell is now in charge of the erection of the Natividad cyanide plant, vice W. B. Washington resigned. The branch road to the Taviche district is being pushed to completion as rapidly as possible. Trains will be running over same inside of four months if the contractor's hopes are fully realized. M. G. Dexter, operating the Atristain claims in the Taviche district, after several months of drifting, has cut a vein at great depth showing excellent ore, none of the samples from which have assayed less than \$60

Special Correspondence.

LONDON.

Kansanshi Copper. — Rhodesia-Katanga Railway. — Metallurgical Difficulties. — Crown Mines. — Oonah Mine, Tasmania. — Metallurgy of Complex Tin Ore. — Tasmanian Gold Mine.

An important step toward the development of Central Africa has just been taken by the decision to proceed at once with the construction of an extension of the Rhodesian railways from Broken Hill to the Congo territory. For some time the owners of the extensive copper deposits in the country forming the watershed of the Congo and Zambesi rivers, situated in the northern part of Rhodesia and over the border in the Congo territory, have been engaged in planning such an extension. Robert Williams, chairman of the Tanganyika Concessions, Ltd., which owns the Kansanshi mines, has been for some time in negotiation with the Belgian company, the Union Minière du Haut Katanga, and with some of the companies that are subsidiaries to the British South Africa Co., with a view of making a financial arrangement by which the responsibilities and advantages could be equitably distributed among the various parties interested. The scheme is now settled, and a company called the Rhodesia Katanga Junction Railway & Mineral Co., Ltd., has been formed. The share capital is £1,510,000, and in addition £625,000 of debentures have been issued. The Tanganyika Concessions is entitled to about one-third of the share-capital, and the remainder is provided for exchange from debentures when so desired by the holders. The present issue of debentures is intended to provide the funds for the construction of the railway. Of this amount £178,000 will be subscribed by the Tanganyika Concessions, and £50,000 by the Rhodesia Copper Co., while £225,000 will be provided by the contractors, Pauling & Co. The Belgian company is also putting up money for the construction of part of the line on its side of the Rhodesia-Congo frontier. The three mines which will be served by this railway are the Star of the Congo, owned in Belgium, the Kansanshi, owned by the Tanganyika Concessions, and the M'Kubwa, owned by the Rhodesia Copper Co. As regards the Kansanshi mine, experiments are still being tried with a view of finding some process which will successfully treat the silicious oxidized copper ores of which the deposits chiefly consist. There are those who advise development in depth, seeking pyritic ores, before any extensive treatment-plant is decided on.

Some weeks ago I mentioned the amalgamation of a number of Rand properties under the name of the Crown Mines Limited, which was perhaps the most important of the consolidations now the order of the day in the Transvaal. This week a statement outlining the future policy and the prospects, prepared by G. E. Webber, has been issued, and some extracts from his report will be of interest. The consolidation involves four producers, the Crown Reef, Crown Deep, Langlaagte Deep, and the Robinson Central Deep, together with a large number of outlying properties only partly developed. To give an idea of the extent and nature of the four producing companies, it may be said that during the 12 months ended November 30 last, the total ore crushed was 1,533,855 tons, the average yield 8.44 dwt., or 35s. 5d. per ton, and the working cost 16s. 3d. per ton. The total net mining profit was £1,327,698. The ultimate life of the properties cannot be exactly gauged. It is, however, fairly well known that, over one-third of the area, the life at the present rate of extraction is something like 21 years. After the amalgamation is effected it is intended to supply additional tube-mills and a larger cyanide plant, and to increase the output to 1,800,000 tons. Eventually it is expected to increase it to 2,000,000 tons per year. At the latter rate the mines explored and unexplored will last 50 years. The estimate of the gold content is lower than the present extraction. The figures given are 7.1 dwt., or 29s. 10d. per ton, and with the economies to be effected the working costs

are expected to be about 15s. 6d. per ton. These figures relate to the portion of the deposits to the north of a dike which appears to cause an upthrow. Though not causing any loss of vein, the presence of the dike makes it advisable to slightly alter the plans of development, and in the meantime hold over estimates of what may be found to the south. The consolidated company will have available cash assets of nearly three quarters of a million pounds, so that no further capital will be required for extension of plant and sinking of additional shafts. The issued nominal capital of the company will be only £931,506, in 1,863,012 shares of 10s. each, and Mr. Webber estimates that about £1,200,000 will be distributed yearly as dividends for an indefinite period. The forward quotations of the 10s. shares is about £7 10s., which means that the yield on the investment will be about 8% per annum. The company intends to inaugurate an amortization scheme, but, as it will be on the nominal capital and not on the market price, the individual shareholder will also have to provide another system for the redemption of his capital out of dividends. The formation of this company will make the largest gold mine on record, and will serve to indicate the immense possibilities of gold mining in the Transvaal.

The progress of operations at the Oonah mine in Tasmania is of great interest. This mine was acquired by the Mount Lyell Comstock Co. and floated in London as a separate company called the Oonah Mines, Ltd., a few months ago. The mine is well known, owing to the occurrence of argentiferous stannite in some of the veins. Stannite is a complex sulphide of iron, copper, and tin, an ore not often found. The mine is situated on the west side of Tasmania, about a mile and a half northwest of Zeehan. There are a number of mineral lodes, and at one time large quantities of valuable silver-lead ores were extracted. The lode containing stannite has not been worked until recently, owing partly to its variable character and partly to the fact that nobody cared to tackle the problem of smelting it on the spot. Close attention has recently been paid to the mine, and the method of treatment by Alexander Hill & Stewart, who have both personally studied the problem on the spot. A considerable amount of development has been done and ore-shoots have been opened in several places. At the present time it is estimated that 8650 tons of ore are ready for extraction, averaging 22 oz. silver, 5.57% copper, and 4.46% tin, and as much again may be put down as 'probable ore.' The question of treating this has been the subject of much experiment, for though the metallurgy of mixed tin and copper ores is perfectly well understood in Swansea and Cornwall, the prices offered by the smelters are not enough. In the old days in Cornwall when the copper pyrite and tin oxide occurring together could not be closely separated by the buddles, very little was paid for the middling, and the smelters made a handsome profit. The mixed ore and the stannite may be treated in much the same way, either by roasting and lixiviating, thus recovering the copper and silver from solution, leaving the tin in the residue, or by smelting. The Oonah company has shipped 300 tons to the United Alkali Co., and 200 tons to Swansea, where it is being experimented on at a small works by the company's metallurgist. The smelting results are of considerable interest, for the metallurgy is being developed by the company in order to reap the whole advantage of the metal-content. Mining companies have usually been content with smelting for copper and silver, and slagging away the tin, but the Oonah metallurgists are adapting the old Swansea method of obtaining two products in the furnace, one a copper-silver matte, and the other a metallic bottom consisting of an alloy of tin and copper. It is found possible by treating 30 tons of the ore, to produce 1¼ tons of matte containing 52% copper, and 80 oz. silver per ton, and 2 tons of argentiferous alloy, containing 58% copper and 36% tin. The matte contains 40% of the copper in the ore, and 16% and 11½% of the silver and tin respectively, and the alloy carries 44% of the copper and 75 of the silver and 84 of the tin contained in the ore. This copper-tin alloy does not bring a high price, for the smelters will give nothing for

the silver, and they make a charge of £8 to £17 per ton. The problem for the company to solve is how to make an alloy of suitable quality for use direct in producing gun-metal and other copper-tin alloys, a problem which at first sight usually seems attractive to the owners of mixed tin and copper ores.

The progress at the Tasmania Gold Mining Co., one of the John Taylor & Sons properties, is not so encouraging as had been hoped, owing to the falling off in the value of the ore, and the presence of barren rock and faults. This company was formed a few years ago to acquire a group of mines that had paid well, but which were no longer workable owing to the vast quantity of water to be handled. An adequate scheme was out of the question unless someone like John Taylor & Sons, with large financial resources, should come to the rescue. The pumping plant erected is one of the largest in the world, and is running without a hitch. The nature of the ore can be gauged by the yearly return for the period ended September 30, when 70,272 tons passed through the battery, yielding by amalgamation, chlorination, and cyanidation a total of 30,302 fine ounces. The total income was £129,118, and the total expenditure £110,927. Practically the whole of the balance has been

The former company has been the most prosperous on the Rand. Since its inception, it has paid out £3,016,750 in dividends, equivalent to 3465% on its capital. But amalgamation in the Central Rand is unlikely to cease here, and, according to report, a scheme is mooted for a consolidation in this area promising to surpass the Crown Mines, Ltd., in magnitude.

It is disappointing to find that only two American firms have entered machines for the forthcoming stope-drill test, out of 23 candidates. The American drills are the Murphy and Waugh. Without prejudice to the trials, which are to extend over many months, and will be influenced by nothing but the results of enduring efficiency under hard working-conditions, it may be mentioned that the Waugh has come to the front rapidly, and has been especially favored for back-stoping up to faults or dikes (where boys cannot be employed to the best advantage). Many of them have lately been introduced upon the French Rand mine, where peculiar difficulties of mining have been minimized by their use, and where both men and management have had cause to be satisfied with their drilling speed. On the average the Waugh puts in well over 20 ft. of hole per machine shift.

The practical services rendered to the industry by our

Cape Copper Co.'s Mines at Ookiep, Namaqualand.

written off for depreciation. The ore reserves are given as 59,125 tons ready for stoping, but at many points are other reserves of partly developed ore. Though the existing levels are giving low returns, the engineers and managers are confident that at the 1375-ft. level better results will be obtained.

JOHANNESBURG, TRANSVAAL.

More Consolidations.—Stope-Drill Competition Entries. — Efficiency of Explosives in Stoping. — Utilizing Planes of Weakness. — Cape Copper Co.'s Report.—Lectures for Miners.— Gold Yield.

The matter of mine consolidations on the Rand has been mentioned in these notes frequently, but it has not been accorded too great attention. Consolidation is the keynote of present history on the field, and is likely to remain so throughout the year. Having seen the completion of the Crown Mines scheme, whereby four famous producers, and large blocks of virgin ground, have been welded into a concern which will certainly win profits exceeding £1,300,000 per annum, students of Rand mining now look for the next group of properties capable of amalgamation upon sound financial lines. That the Ferreira and Ferreira Deep will shortly be united is an open secret. Present results from these two renowned mines are as follows:

	Stamps	Yield per month	Profit per month.
Ferreira	120	£58,000	£36,000
Ferreira Deep	160	80,000	51,000

technical societies have been well illustrated of late by the discussions held by the Chemical, Metallurgical & Mining Society upon problems of underground work. A few years ago this organization confined itself to questions relating to ore reduction and gold recovery, but the extension of its scope to mining has unquestionably stimulated the scientific investigation of many difficulties and experiences. It is remarkable that even today these open debates should be throwing light upon fundamental conditions of mining practice. Recently a paper was read upon 'The Theory of Blasting with High Explosives' by E. M. Weston. In the discussion, the theme has been elaborated widely, and two mine managers have given lengthy contributions dealing with the economical use of explosives in stoping and development, and pointing out the advisability of taking advantage of certain petrological features in the 'banket' too frequently neglected. This latter point is most fully discussed by H. M. Thomas, who urges that the primary consideration should be in the observation of any tendency of the conglomerates and country rock to break more easily in one direction than another. At first sight, this recommendation may appear rudimentary, but in reality it involves the application of greater intelligence than miners are apt to exercise. Bedding-planes are not referred to, for these are naturally utilized, by the most inexperienced, wherever they appear, and are commonly reflected in the good foot or hanging wall of underground workings. But attention is directed to the so-called 'fracture-planes' occasionally cutting vertically through the strata at right angles to the strike, the presence of which may be demonstrated by the

breaking of the ground in mining operations. The full significance of these lines of weakness—probably of appreciable importance only in certain places—has not been symmetrically determined. The inclination of the stope-face to the plane of the reef is planned in Rand mines according to the requirements for underhand, overhand, or breast-stoping, and to facilities for shoveling the broken rock to the boxes. But Mr. Thomas claims that the trend of these slight 'fracture-planes' should be a guiding factor. Clearly, if there is a regular sequence of such planes running through a stope, the duty of a given quantity of explosives is greatly increased by putting in the holes parallel to them, while, correspondingly, their neglect may be the cause of 'bull-ringing' (that is, the blasting out of the burden only at the bottom of the hole, with the collar left intact), or of breaking out only the top part of the burden. Upon the Jumpers Deep, of which Mr. Thomas is manager, the system of taking the utmost advantage of these fracture-planes is being put into practice on a scale promising to conclusively reveal its economic benefits.

The comments of Stuart Martin, the mining engineer of Welsh colliery experience lately appointed consulting engineer to Wernher, Beit, Eckstein & Co., were interesting. After pointing out the unmistakable advantages of slips and cleavages in breaking coal in South Wales, he remarked that the first thing he did upon visiting Rand mines was to enquire which was the right direction of carrying the stope-face in order that rock might be broken skilfully. He gathered that, beyond the occurrence of occasional slips and the consideration of shoveling efficiency, the matter was held to be one of small account. He followed up this question of the line of weakness from one mine to another, and not until he reached the Jumpers Deep did he find it to be under serious investigation.

In common with all other copper producers, the Cape Copper Co. suffered severely during 1908, owing to the market collapse, and, having no appreciable amount of gold in its yield, it has been obliged to present a statement for the year even more strikingly unsatisfactory in comparison with previous returns than has been possible with many big producers in other countries. The profit realized reached a total of £144,366 for the financial year, against £379,910 in 1907. Of this decrease £191,902 is due to the reduced value of copper, but £24,153 of it must be attributed to the Tilt Cove, Newfoundland, workings. The output from Ookiep and Nababeep was 4356 tons—27 tons higher than the figure for the preceding year. Records of ore mined show that 13,927 tons, containing 15½% copper, were drawn from Ookiep and 59,348 tons, containing 4.90%, from the Nababeep North and South mines. It is reported that prospecting operations have been continued as vigorously as ever, but have still failed to disclose a new source of ore-supply to take the place of the nearly exhausted Ookiep. This wonderfully rich mine was discovered over 50 years ago, and has since turned out nearly 620,000 tons of ore, averaging 19½% copper. A general view of the camp is reproduced herewith, giving a good idea of the sterile character of this Namaqualand district, which has been so little beautified during a half-century of settlement, owing to the lack of a regular or beneficial rainfall.

Recognizing the utility of technical education among miners and the difficulty of attracting busy workers to the evening classes held at the college in Johannesburg, Prof. John Yates has just formed a scheme for the delivering of lectures at various centres along the Reef. The hope has been expressed that such a scheme might result in a marked diminution of our high accident-rate, but this anticipation is far too sanguine. It is, however, clearly unnecessary to seek revolutionary changes of efficiency as the probable outcome of the scheme to justify its experimental introduction. The opinions of numerous managers have been obtained on the question, with the result that the principle has been warmly commended, but past experience has shown that it is more necessary to provide opportunities attractive to the mine workers than merely to satisfy the academic ideals of the men in control. In

spite of the fairly rigorous Government examinations, to be passed by mine foremen as well as by managers and surveyors, only a small percentage of the miners can be induced to trouble themselves in the quest of knowledge about such 'fancy notions' as the principles of blasting, ventilation, etc.

Owing to the inclusion of large amounts withdrawn from the gold reserve, the Transvaal's December output becomes a 'record' at £2,806,235. This brings the year's total to £29,957,610, or only £42,390 below the round sum of thirty millions sterling. New mills are destined to ensure a further substantial increase for the current year.

BISBEE, ARIZONA.

General Geology of Courtland District. — Development by Copper Queen and Calumet & Arizona. — Railroads Building.

Courtland, the new mining town of Cochise county, Arizona, is 36 miles northerly from Bisbee, 45 miles from Douglas, 10 miles from Pearce, and 5 miles from Gleason. The mineral ground occupies a spur of the Dragoon mountains and overlooks the White Sulphur Springs valley that stretches from Douglas to Willcox. The country comprises limestone, quartzite, and porphyry. The orebodies are mostly along a contact between limestone and quartzite, striking northwesterly, though there is one mine that appears to be mostly in porphyry, namely, the Great Western. It is considerably developed and was a shipper of ore as early as 1894. The Leadville claim was located 20 years ago, and has been slowly undergoing development since then and has shipped some ore. Recently the Calumet & Arizona Co. and the Copper Queen Con. M. Co. acquired property in the district, and the former, especially, has pushed development with vigor. The Germania shaft of the C. & A. has been sunk to a depth of 410 ft. on the orebody, development from it amounting to about 7000 ft. The ore has a dip of 23°, and was reached at 240 ft. from the surface. In the new Mary shaft of the Great Western the same orebody was struck at a higher level, 150 ft. below the surface. The April Fool shaft of the C. & A., 1000 ft. northwest of the Germania, which also belongs to the same company, has reached a depth of nearly 200 ft., and the expectation is to cut the same 'contact' later. The Copper Queen Co. is sinking the Silverton shaft 300 ft. east of the Great Western's Mary shaft, and has acquired and is developing the Casey group, lying west from the C. & A. holdings. The Casey shaft is down 250 ft., with levels in limestone from the 150 and 250-ft. stations. The ore is in a nearly vertical vein in lime, and is different from the great contact-deposit which may be penetrated at greater depth. The ore in the principal contact-vein, as is best illustrated by conditions in the Germania and the Mary, consists of copper carbonate, oxides, and chrysocolla, in a gangue of quartzite and altered lime. In the last two mines there are large bodies of pitch-colored, hydro-silicious material, locally termed 'black chrysocolla,' occurring altogether on the limestone side of the contact. It should be stated in this connection that the quartzite overlies the limestone, and the chrysocolla, being a secondary deposit, is found nearest the limestone foot-wall, with the oxides and carbonates above it. This vein, or contact deposit, is 80 to 150 ft. thick, the blanket of pay-ore being from 30 to 70 ft. thick; and it is authoritatively stated that this great body of ore assays from 7 to 8% copper. A big tonnage of ore of this grade now seems assured. The work on this vein follows the dip, which is 23°, a distance of 2100 ft., including work on the Germania and the Mary. The original Great Western group is about a mile south of the part known as the Mary mine. A new 288-ft. shaft has been sunk on the original group, and from it cross-cut levels are being driven into the ground below the old workings. This group has an orebody on the contact between limestone and porphyry, and has no direct connection with that opened by the C. & A. The Great Western belongs to Young Bros., of Clinton, Iowa, W. J. Young being the manager. The Leadville is managed by William Holmes, the original locator, who has

developed a strong vein of copper sulphide ore on a zone farther west than those just described, but having the same general strike. Here is a quartzite-porphry contact, having but slight inclination from the vertical. The vein is opened by a 300-ft. shaft, from which extend 3000 ft. of lateral development, showing chalcopryite ore from 5 to 8 ft. wide, said to assay 9% copper and to contain some gold. The Leadville is 3000 ft. west of the Germania and 130 ft. higher than the latter. The El Paso & Southwestern Railway Co. is preparing to build a branch line into Courtland from Douglas, over which these ores will be hauled to the Douglas smelters; and the Southern Pacific Co. is extending its Cochise-Pearce line toward Courtland, the plan being to continue it into Sonora. There are said to be 400 men employed at the Courtland mines, and the district contains 1500 people.

ALAMOS, MEXICO.

Railroad Facilities. — Alamos Silver-Copper Co.—Quintero Mine.—Zambona Development.—Pulpito Vein System.

Within the last year the Southern Pacific Co. has completed a branch railroad 60 miles long to Alamos, starting from Navajoa station, on the main line of the Cananea, Rio Yaqui & Pacific. This road affords transportation facilities for Alamos and Minas Nuevas, where exists one of the strongest contact-veins of southern Sonora. The district is famous in mining history, and the advent of the railroad is bringing about that strange commingling of the old and the new that is seen in so many places in Mexico. The great lode of silver and copper ore that attracted the Spaniards in 1720 has more recently attracted American and French investors, whose operations have been marked by a considerable degree of success. The mineralized zone, containing several parallel veins, is on a contact between granite and porphyry, the principal mines opened thereon being the Promontorio, Quintero, Zambona, Santo Domingo, and Pulpito. All these are close to Minas Nuevas, an ore-shipping station 10 miles from Alamos.

The Promontorio belongs to the Alamos Silver-Copper Co., of Philadelphia, and is managed by Jos. L. Overmuller. The main vein on this group stands vertical, and has a width of 20 to 40 ft. The ore carries an average of 35 oz. silver and 2½% copper, and contains a great deal of tetrahedrite accompanied by silver. The orebody is opened by an adit that gives a depth of 300 ft., and there are workings extending 300 ft. below the adit level. This company recently began operations and has been putting the mine in order. They have a dump containing 150,000 tons of milling ore, and have bought the equipment for a concentrating plant, which is soon to be erected. A smelting plant to produce copper matte is being considered.

The Quintero belongs to a company of French people. The mine has been developed to a depth of 1600 ft. on one of four veins embraced within the property. There is a concentrating plant and a single-track copper smelter, now temporarily closed. The property is managed by Carlos Mahaut. The Zambona Development Co. of Los Angeles operates the Zambona mine, A. J. Yaeger being the manager. The workings are 700 ft. deep, with extensive lateral development exposing an orebody of great width. The ores are those of silver and copper, characteristic of the district. The old concentrating mill has been in operation until recently, and a new mill, of 150 tons capacity, is being erected. The Santo Domingo occupies ground between the Quintero and the Zambona. It is controlled by the Sonora Central Mines Co., which owns 4000 ft. on the strike of the mineral zone. The principal shaft is 360 ft. deep, and from it there are three levels in ore. A winze is being sunk from the 300-ft. level at a point 1200 ft. from the main shaft. There is a steam hoist at the main shaft and an air-compressor and drills are to be installed. Plans for a concentrating mill are being drawn. The ore is composed of quartz and calcite, assaying 16 to 18 oz. silver per ton and 5 to 6% copper. Near the surface there is some lead, but this is not in evidence on the deeper levels. There are

streaks of argentite and tetrahedrite that assay thousands of ounces of silver per ton and as high as 35% copper. J. R. Hendra is superintendent, E. A. Haggott of Los Angeles being consulting engineer.

The Pulpito ground covers an extension of the Quintero vein-system. It belongs to Antonio Goycoolea and sons, who formerly owned, but sold, the Zambona and Purísimo mines. They are driving a cross-cut level which will intersect the Pinta, Pulpito, and San Francisco veins of the system at 700 ft. The cross-cutting has progressed 1000 ft., 10 by 10 ft. in cross-section, and the intention is to drive over 3000 ft. and lay a double-track for ore cars. Ore taken from the Pinto vein where it is 2 ft. wide assayed 8½ kg. silver per ton and 41% copper. A 500-ft. drift was driven on the Pulpito vein, and from this drift a cross-cut was made to the San Francisco. Ore from the latter assayed 150 kg. silver and 22% copper. The silver is present as argentite, and the copper ore comprises both sulphide and carbonate. Manuel Goycoolea, who has the management of this and of other properties, states that mining on the Zambona, Quintero, and Promontorio began 200 years ago, and that members of the Goycoolea family have been mining at Alamos during the last 100 years. The little city of Alamos, founded in 1720, rests on the granite and porphyry hills through which the mineral zone strikes. T. P. Brenigar, in charge of the Nuevas-Promontorio group, owned by Kansas City people, has struck a vein of ore believed to be an extension of the Quintero and Zambona veins, this location being some distance south of those mines.

TORONTO, CANADA.

Dominion Iron & Steel v. Dominion Coal.—Notable Decision.—Gowganda Boom.—Cobalt Silver Queen.—Cobalt Development.

The decision of the Imperial Privy Council in *Dominion Iron & Steel Co. v. Dominion Coal Co.*, appealed from the Supreme Court of Nova Scotia, caused excitement in financial circles. The combined capital invested in the two companies amounts to about \$57,000,000. The steel and coal companies were closely associated from the outset, the former being organized by the same group of capitalists that controlled the coal company. For a time the steel company held a lease of the coal company. This terminated in 1903, and a contract for 90 years was entered into, by which the coal company was to furnish the coal required for the steel plant at Sydney, Nova Scotia, at \$1.24 per ton, with an additional 4c. per ton for the use of cars. Friction arose over the unsuitability of coal furnished on account of its sulphur. In the fall of 1906 the supply fell short, and after a protracted controversy the coal company declared the contract at an end, alleging that the steel company had violated it by rejecting a quantity of the coal supplied. Thereupon the steel company brought suit for damages and obtained judgment in the Nova Scotia courts. An appeal to the Privy Council has resulted in sustaining this judgment and remitting the case to the Nova Scotia Supreme Court to assess the damages. As the contract embodied a description of the steel company's plant, the court ruled that this sufficiently indicated the purpose to which the coal was to be put, and placed an obligation on the coal company to supply suitable fuel. The damages will undoubtedly be heavy, the principal item being the difference between the contract price of \$1.24, and the price which the steel company has subsequently been compelled to pay. The bill, as figured by the steel company, up to January 31, amounts to \$3,901,663.

Interest continues to be centred on Gowganda. Many new ventures based on claims in this field are appealing to the public. As the snow is deep over most of the country, and real discovery impossible, prospectors are staking claims and filing affidavits on the chance of being able to 'make good' when the spring arrives. In the meantime, many of these wild cat locations are bought by speculators without assurance that title can be perfected. The foundation is being laid for as fine a crop of swindles and lawsuits over title, as resulted from the Cobalt and Larder Lake

booms. Just now there is a rush to forward machinery and supplies into the camp before the winter breaks. The Gowganda mining division has been formed out of territory lately embraced within the limits of the Montreal river and Temagami forest reserve divisions. This gives a separate recording office to the new camp, and will considerably facilitate recording and inspection of claims. Harry Sheppard of Orillia is appointed recorder, with temporary headquarters at Smyth or Elk City, until an office can be provided at the Gowganda town-plot.

The slump in the stock of the Cobalt Silver Queen has been explained by the passing of the dividend. While the company, as previously stated, has ample funds on hand to pay a dividend, it was considered advisable to husband resources for development work. The Right of Way has been put on a 6% quarterly dividend basis. A 9% bonus has been declared for the current quarter. The value of the year's output was \$218,000. Henry S. Hill and a syndicate of Buffalo capitalists have taken up an option on the Tallen claim, South Lorrain, where a shaft is down 50 ft. on the calcite vein. As many as 12 veins have been found in trenching. The Station Ground Mining Co. of Cobalt is negotiating with the Cobalt Lake Co. for an agreement by which they can use the workings of the Cobalt Lake to prospect their adjacent holdings. A strike was recently made at the Crown Reserve in the north cross-cut at the 100-ft. level, consisting of two veins about 3 in. wide and 15 in. apart. One assays 12,000 and the other over 2000 oz. silver per ton. At the La Rose, in driving on the McDonald vein, ore assaying 10,000 oz. silver per ton and 6 in. wide was struck. The shaft on No. 3 vein is being put down from 125 to 150 ft., the vein being 3 in. wide and yielding ore assaying 5000 oz. per ton. In the City of Cobalt rich ore has been found at the bottom of a winze from the main shaft 225 ft. from the surface. The vein is 9 in. wide, with slabs of native silver and argentite.

BUTTE, MONTANA.

Hearing in Smelter Smoke Case. — Elimination of Arsenic. — Butte-Montana Re-organization. — Tuolumne Mine.

The method for the elimination of arsenic from smelter smoke in use at the Washoe smelter at Anaconda does not prevent the escape of arsenic from the stack. While the company saves about two tons of pure arsenic daily, there escapes into the atmosphere an additional 10 tons of As_2O_3 . At the Great Falls smelter of the Amalgamated Copper Co. a friction method for elimination of the arsenic is being installed in connection with the new high smelter-stack, and if it proves successful it will be substituted for the system now used at the Washoe, although the change will mean an expenditure of between \$2,000,000 and \$3,000,000. These were some of the interesting facts brought out at a supplementary hearing before Judge Hunt of the United States Court, conducted in an effort to find a means for further reducing the smoke nuisance. The company made many experiments with electricity as a method of removing the arsenic from the smoke. F. G. Cottrell, of Berkeley, Cal., who has an experimental plant of that character at Selby, Cal., was offered \$200,000 by the Amalgamated Co. if he would perfect a method that would successfully remove the arsenic from the smoke, but he would not guarantee his method, saying that during the operation of his plant at Selby he had encountered mechanical difficulties of so serious a nature that he doubted if his system could be applied to the Washoe works. An effort was made to have him carry on his experiments at the Washoe and Great Falls smelters, but he preferred to experiment at Selby. President Roosevelt has instructed government experts to investigate the method of elimination used by the Tennessee Copper Co. at Ducktown with a view to compelling the Amalgamated to install the same system at the Washoe smelter, but F. J. Falding, a chemical engineer of New York, who evolved and constructed the system at Ducktown, testified before Judge Hunt in the Washoe hearing that the system was impracticable for the Washoe smelter.

He declared that the problems at Anaconda were not at all like those at Ducktown, and the Washoe plant is at least six times as large as the plant at Ducktown. Mr. Falding is engaged in experiments at the Washoe, but he said that the method at present used at that smelter is the most complete and efficient of which he has any knowledge. It is the method used at other smelters where an attempt is made to eliminate arsenic, the method being by cooling and retarding the gases and disseminating them by means of a high stack. E. P. Mathewson, superintendent of the Washoe, said the company had spent hundreds of thousands of dollars in scouring the world for scientific information on the subject of smelter-smoke and the elimination of the poisonous substances. Every known method has been investigated, including all the cooling processes, spraying by water, by the admission of air, by radiation, by freezing; the bag-house process, electricity, friction, filtering the gases, decreasing the velocity of the gases, and by centrifugal gas cleaners. The spraying method can be used only at small plants where the volume of smoke is comparatively insignificant. At a plant like the Washoe the acid mud created by the spraying would be of so great a volume that it would be more dangerous than the smoke itself, as it would have to be allowed to pass into the streams. To install such a plant would cost \$3,000,000, and not enough water would be available to operate it. The bag-house method is impracticable because the acids from the copper ore would destroy the bags. Such a plant would cost \$2,750,000, with an operating cost of \$1850 per day, while the arsenic recovered would be worth \$204. Mr. Mathewson detailed the results of the company's investigations and tests of other methods and found them all unsuited. The present methods employed at the smelter were installed on the recommendation of Stuart Croasdale of Denver, endorsed by the company's consulting engineer, D. W. Brunton, after the latter had made a tour of Europe, where he studied the smelter question. The smelters using the process are one in Utah and another at Everett, Washington. The hearing before Judge Hunt will be taken up again on April 19 in Butte.

Of the ore received at the Washoe smelter 90%, or 9000 tons daily, is concentrating ore, and only 10% goes direct to the furnaces. As high as 2½% of arsenic has been found in the ore, and from that down to a trace. The largest percentage of arsenic is found when the ore contains enargite.

Another company that has taken the unpopular step of reorganization is the Butte-Montana Mining Co., owner of the Alex Scott and Annie mines, the former a well situated copper property, and the latter a silver mine of small value in the northern part of the Butte district. Some time ago some Duluth and Pittsburg men secured an option on a control of the company's stock, the company being capitalized at 1,000,000 shares of the par value of \$1 per share. The new interests proposed to increase the capitalization and raise the par value to \$10 per share. Opposition was manifested, and now comes the information that a new company, the Butte Alex Scott Co., has been organized with a capital stock of \$1,250,000, divided into shares of \$10 each. The purpose is to deliver to the Butte-Montana Co. 50,000 shares in payment or exchange for its property, in addition to which the debts of the old company will be paid. The Duluth people will take 50,000 shares at \$2 each, paying into the treasury \$100,000 at once, and will advance the remaining \$400,000 whenever called for. It is understood that Butte-Montana stock may be exchanged for Butte Alex Scott stock at the rate of 20 shares for one share of the new.

The shaft of the Tuolumne mine has reached a depth of 1300 ft., and it is expected that cross-cutting at 1400 ft. can begin about April 1. On the 1000-ft. level the vein has been opened by drifts, but it does not contain good commercial ore, though the vein is large and strong, having a width of 26 ft., and it has been opened for 100 ft. in length. A station has been cut at 1200 ft. It is believed that on the 1400-ft. level the vein will be found rich. The company has just installed a new battery of boilers and a new compressor of 20-drill capacity.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

With the four weights of 1, 3, 9, and 27 lb., any unit number of pounds may be weighed between 1 and 40.

Brake horse-power is that which a motor can exert in doing outside work, and in the case of a steam-engine is less than the indicated horse-power by the power required in the engine to overcome the friction of its parts.

Slags containing much manganese retain silver. This is probably due to chemical action from the presence in the slag of the silicates of the sesquioxides ($xR_2O_3 \cdot ySiO_2$), and the formation of Mn_2O_3 occurs under such conditions. The reduction of this sesquioxide to protoxide would at the same time reduce other metals and render the bullion base.

Bronzes are notoriously difficult to cast, and it is a general practice to alloy 1 to 2% zinc in them for the purpose of getting better castings. It probably acts as a mild de-oxidiser. Zinc is often added to cheapen common bearings. Anything from 0 to 14% zinc, and from 8 to 18% tin is used, but those bearings high in zinc cannot be recommended for good work, as they wear badly.

Rock decomposition forms soil-grains in which the sizes bear certain definite relations to their chemical composition; for example, the lime-content decreases with the size of the particles, while the potash increases as the particles decrease in size. This, of course, applies to sediment which has been sorted by transporting waters. Phosphoric acid and magnesia are irregularly distributed, although there is a tendency to enrichment in those substances with increasing fineness of the particles. In untransported soil residues upon decomposing crystalline rocks the quantity of lime and potash are notably less than in the parent rock.

Sound from a moving source is heard by a person at a fixed spot different from its true note at every moment. As the source approaches, the length of the sound-waves is apparently decreased, and the length is similarly increased when the source is receding. Hence to a person at a station, the whistle of a passing train will sound higher than its true note while arriving, but lower when departing, and only correct when actually in front of the observer.

A Telford road was constructed by the United States Government during the administration of Andrew Jackson. It was built as a military highway, and was known as the National Turnpike, extending from Baltimore to St. Louis, approximately 1200 miles. It was one of the best examples of road-construction in the world. It was a true Telford road except in the prairie regions of Indiana and Illinois, where recourse was had to gravel. In some parts of

the Allegheny mountains the lower courses have become so consolidated by natural cementation that they resemble conglomerates, and are often so firm that a fracture will extend across the rock-fragments.

Mining claims in Peru are based upon a unit of 2 hectares (1 hectare = 2.47 acres). Claims to which patent is obtained are held by as indefeasible a title as real estate, but the mine-title is distinct from the land-title. All unfenced land is open for prospecting and location of claims, whether owned privately or not, but permission to prospect must be obtained from the owner if the land be fenced. A license may be obtained from the proper authority to prospect fenced lands, but a deposit as a guarantee of indemnity for damages must be made. There is no discrimination against foreigners. The annual tax is 30 soles (about \$24) on each claim.

Stoke-room competitive firing was inaugurated by the commander-in-chief on the cruise of the U. S. fleet around the world. The spirit of rivalry between the engineer-forces on the different vessels caused them to put forth their best efforts to reduce coal consumption. This has been effected to the gratifying extent of 20%. In a similar way efficiency has been improved in mining centres, notably in Western Australia, where for many years the production per man for each mine has been posted in the men's change houses; and the emulation among the miners brought about all the satisfactory results that could be desired.

Hydraulic horse-power may be one of two kinds. The first is the simpler, and is that due to position. It is equal to the product of the quantity of water available (in cu. ft. per sec.) multiplied by the weight of a cu. ft. of water (62.3) multiplied by the head in feet, divided by 550. The second is exemplified by power developed at the nozzle of a jet under pressure, and is equal to the quantity of water passing through the nozzle (in cu. ft. per sec.) multiplied by 62.3, multiplied by the square of the velocity of the jet, divided by 35420. The determination of this velocity cannot be expressed in quite simple terms, as it is dependent on lengths and diameters of pipe used, and on the internal friction.

The Panama Canal, if excavated to sea-level, would necessitate a cut approximately 365 ft. deep. The rock through which the cut would be made is decomposed, and disintegrates readily when exposed to atmospheric agencies. The slope necessary to give protection against destructive landslides under such circumstances would so enormously increase the cube of excavation as to make the cost prohibitive. The alternative method for a sea-level canal would be to excavate the sides in steps or terraces and face with concrete retaining-walls. This would be almost equally expensive. The objection to the lock-canal is, first, the doubt as to the stability of the foundations for the locks and dam, and second, the perpetual cost of operation, and loss of time in transit by ships.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Engineer as a Financier.

The Editor:

Sir—I have read with much interest, some sadness, and a great deal of curiosity the various letters that have appeared under this head. Interest, because the study of mankind is always interesting. Sadness, because it is somewhat saddening to see gentlemen who stand at the head of a great profession, and whose names are names to conjure with, trying to justify that, which in their inmost consciousness, they know cannot be justified. Curiosity, because I am curious to see how far they will succeed in deceiving themselves.

Much has been written, and yet the most that has been said is that there is no legal nor moral wrong, in a mining engineer taking a contingent fee, or reporting on a mine in which he is interested, "provided that he does not let his personal interest bias his judgment;" and this was said by the MINING AND SCIENTIFIC PRESS. But, Sir, is there not another view-point, outside the legal and moral one—the view-point of *honor*? There are certain things that are honorable, man may not do; and this practice is dangerously near the line, if not outside it altogether. There are many things that are quite innocent and harmless in themselves, that may not be permitted to men in certain positions. A judge may not try a case in which he is even slightly interested, although he may be quite capable of rendering a fair judgment.

Does the engineer owe nothing to the public, to his name, to his honor? I think he does, especially when he knows that his report will be used to induce the public to invest; and more especially when he knows that that report will be presented to the public as coming from a disinterested source. Suppose a client came to one of your eminent contributors and asked his advice about investing in a certain mining property, in which he—the mining engineer—was not interested, and showed him a flattering report on the mine signed by an equally eminent engineer as himself, whom he knew was interested in the mine in question. What advice would he give to his client? Something like this I fancy: "This mine has a good reputation, and this report is an excellent one, and the name signed to it should be a guarantee; but I suppose you are aware that he is heavily interested in this particular mine. If you are thinking of investing, it would be the part of wisdom to get a perfectly disinterested report." Would the client be quite so keen to invest on the strength of the report if he knew that it was open to the suspicion of bias? Is it right for a man to act as a judge in his own case? And a mining engineer passing on a mine is acting strictly as a judge.

One thing more: does not the very elaborate spe-

cial pleading, shown in the letters of your correspondents, show that there is something that needs explaining; something that is not quite, er—quite, er—er—well, not quite nice, not quite in accordance with the highest ideals; that the doing of this thing is not quite clean, not quite to be reconciled to a high sense of honor. The question to be solved is not, Is it legal? Is it moral? but is it honorable. Money may be made by this practice, it is true, but does money compensate for a loss of honor? After all is money the only criterion of success? The mining engineer should, above all others, be "*sans peur et sans reproche*"?

CHAS. R. GENT.

Trimmer, California, January 30.

[In view of the quotation made by Mr. Gent, which places the MINING AND SCIENTIFIC PRESS in a position the exact opposite to that which it had assumed, we beg to quote from our editorial printed on July 18, 1908: "There is no moral wrong in an engineer holding an interest in a property which he has examined; there is not even any moral obligation which could require an honest man to decline contingent fees. * * * * * Therefore it is not a case of pure ethics; but in deference to the prevailing adamic weakness, and to the need of so protecting the investing public that the mining engineer may, in furtherance of his ultimate pecuniary advantage, win confidence and have his services regularly esteemed and well remunerated, the matter assumes importance as a necessary part of a code of professional ethics. An engineer should not work for contingent fees. We know that because of the errors it continually leads to, and the unscrupulous class of promoter with whose operations the practice is perpetually associated. It is a custom that prevails in connection with those evils that walk in the darkness within the realm of mine-promotion." We endorse the spirit animating Mr. Gent's manly plea for an ethical standard for the mining engineer, but we may also ask how far mining engineering has yet put on professional consciousness in the recognition of what a profession really is?—EDITOR.]

The Engineer as a Financier.

The Editor:

Sir—On the question of professional ethics I would endorse your position rather than that of Mr. Hammond or Mr. Finlay. All that Mr. Hammond says about loyalty to the employer, the double capacity of an engineer as an employer, the expert witness, commissions on machinery, the statement that most of the swindling is done by laymen and not engineers, the duty to the investing public, and the engagement of local engineers as colleagues, is sound, and excellent; and his expert's Golden Rule is magnificent and worthy of being printed as an emblazoned maxim:

Tell unto others now whatsoever you would not have them tell on you (with unjust misunderstanding and scandalous comment) hereafter!

Commissions on sales and contingent fees seem to me to group themselves together as related to this

discussion. What Mr. Hammond and Mr. Finlay have said on these subjects, I regard as altogether untenable, unprofessional, and dangerous. Taking a commission from both seller and buyer is anomalous from the fact of making it a temptation to put the valuation as high as possible; and a flat fee from both parties is wrong if either is contingent; if not, it could be excused only by the frank understanding with each party that the other was also paying. Surely that must be a rare instance indeed; so rare as to make it farcical as a defense of professional laxity. Mr. Hammond proposes to justify accepting "compensation from the promoters, provided, first and without qualification, that full publicity be given to the nature of his connection with the enterprise." Now when this is done it virtually becomes a vendor's report, and would be practically so considered by any sensible buyer, and must be placed under that heading. Making the contingent fee dependent on the "subsequent success of the undertaking" seems utterly impracticable. How long are you to wait to prove the outcome? Questions of blame for failure and delay and of unforeseen contingencies, etc., would be fruitful sources of misunderstanding and litigation.

Taking advantage of knowledge gained while under pay in one mine, to secure an ownership or lease in neighboring ground, without first imparting the full information to the employer, and giving him the refusal of the same opportunity, or holding an interest in a lease on the same property that pays the engineer a fee for consulting work, constitutes a species of commercial activity belonging to the same category as contingent compensation.

I would contend that no standing is high enough, no personal character strong enough, to justify a contingent compensation. To make personal character a guarantee for a questionable use of professional advantage is begging the question; it does not establish a rule or code to show how near the danger line some may go. Whoever heard of a judge, however high and honorable his standing, presuming to sit in a case in which he had a pecuniary interest, direct or indirect? Yet the circumstance would be no worse than that of an engineer taking a contingent fee. Doctors do frequently own interests in drug-stores; and the culpability of the situation is disclosed in the fact that they invariably keep such interests a secret from the general public.

But an engineer may well cast his fortune with an enterprise, as advocated by Mr. Hammond, as advisor or manager, provided that his compensation comes from the new owner and is in no way contingent upon the transfer of the property.

Mr. Finlay says that an engineer's "activities in the direction of speculation in stocks should be no more limited than those of any other man of common sense." This sentiment I regard, professionally, as most culpable. You, sir, say that "personal speculation in mining shares saps the foundation of professional integrity." I agree to this, but the thought does not apply so fully under this head as to a later paragraph. I think that a well defined line should be drawn between speculation in a ven-

ture on which one is professionally engaged and any other stock or mining transaction. This is a distinction which, so far, no one has made in this discussion. The limit is that professional engagement and pecuniary personal speculation shall not be tolerated together in connection with the same enterprise. The fact that, under this rule, an engineer loses his very best chances of speculation cannot excuse an infraction. I hold that an engineer has an unquestionable right to speculate in the stock of any concern on which he is not professionally employed, that he may even act as an absolute promoter, or make a sale on commission, as long as he informs the purchaser in regard to his connection with the enterprise, makes no report himself, and insists that the buyer shall employ a disinterested expert of his own choice; but whether it is good professional policy to do these things, I shall discuss later. The doctor may honorably own a drug-store in another town, where his prescriptions could not be sent. The stock-broker has the right to speculate in shares provided that, when he is buying or selling any particular stock for himself, he notifies any client who chances to apply for that particular stock, and advises him, in that particular instance, to go to another broker. This contingency is covered by Mr. Hammond's scheme of full publicity.

Granting an engineer's right to speculate in stocks, or to act as a promoter when not in connection with a professional engagement, there still remains the question of good professional policy and all of the really fine points of professional ethics.

If we are to follow the profession for life we must forego some of the "inalienable rights" of the financial engineer. It is a mistaken idea that the employer of professional service looks for one who is himself exhibiting great personal financial prosperity; my observation is that too keen an exhibition of the money-making quality rather begets distrust. The miner or the investing public is more sensitive to professional constancy than some seem to perceive. Under this head your sentiment, "participation in company finances undermines professional ethics and that personal speculation in mining shares saps the foundations of professional integrity," applies with full force.

Even when considered with reference to pecuniary income the question should be treated from the standpoint of a business that is to yield a revenue throughout an active life, and not as only a stepping-stone in finance. We do not have to reflect long to recall some engineer whose commercial activity readily betrayed the fact that he had taken hold of the profession as a vaulting pole to be quickly dropped when it had served its purpose. A good simile is found in mining operation: The financial engineer is the lessee who sinks a little shaft, without timbering, if possible, leaving rubbish in every drift, gouging out the first bunch of ore found, by underhand stoping, or any other way, until finally the ground is left to cave. The thoroughbred professional man represents the owner who puts down a well timbered shaft, of sufficient size and equipment, does his work in miner-like fashion, so that the

place may be worked as long as it will yield any profitable ore. Our commercial engineers at least lay themselves open to the suspicion of treating the profession after the manner of the lessee. In a discussion on the ethics of the situation, at least, I think that we should take the stand of the owner and ignore the lessee.

A vendor's report and relations to the public are two subjects covered by the same principles and should be treated under one head. A preliminary or vendor's report is, I think, an absolutely legitimate performance for an engineer for the reason that, when made in the proper form, its character as a seller's description of his property is apparent, and it frankly challenges verification by any other engineer who may be chosen by a purchaser. The engineer protects the public and himself at the same time. What you have said on this point well covers the subject. It is also illustrated by the well remembered Shakespearian proverb: "To thine own self be true, and it must follow, as the night the day, that thou canst not then be false to any man."

There is no part of this subject more worthy of consideration than that of demanding sufficient time to do justice to professional work. The young engineer in particular can study this subject with profit; but the question never vanishes throughout the longest professional career. The engineer is continually approached to make some report, or to act as an expert witness, without sufficient time for preparation. Sometimes from shrewd motives of economy, the employer comes with the statement that the work must be done by a certain date; sometimes the cunning promoter endeavors to cut the time short in order that the weak points may escape observation; but perhaps more often than otherwise, the employer, through pure ignorance of the time necessary, delays speaking to the engineer until the expiration of an option or the date of a court trial is too near at hand. The temptation is great; it is comparatively easy to stay the conscience with the thought that an engineer cannot report on more than he is able to see, nor be held responsible beyond the points covered. Nevertheless right here lies the greatest danger and many pitfalls. If he cannot do justice to the case he cannot do justice to himself. He must decline employment to stand by his colors. I can think of no branch of the subject in which professional ethics comes closer to every day practical application.

Denver, February 6.

Power in Stamp-Milling.

The Editor:

Sir—In your issue of February 6, I notice an article by H. Haas referring to my article, 'Stamp-Mill Practice on the Mother Lode.' Mr. Haas questions the correctness of my statement regarding the horsepower used in operating our new 20-stamp mill; he states authoritatively that $42\frac{1}{2}$ hp. is required to operate twenty 1000-lb. stamps, dropping 106 times per minute with a drop of 7 in.; with an additional 10 hp. to operate the 12 Frue vanners; making $52\frac{1}{2}$

hp. to operate the entire 20-stamp mill. After an experience of over ten years in mill-practice on the Mother Lode, I am compelled to differ with Mr. Haas and his authorities. The actual power required to operate the 20 stamps in question together with the twelve 4-ft. Frue vanners is $42\frac{1}{2}$ hp. It requires only $\frac{1}{2}$ hp. to operate one 4-ft. Frue vanner, provided the machine is kept in good running order, while if that care is neglected, it would undoubtedly require more power.

Regarding the comparison between the old and new mill, as suggested by Mr. Haas, I may say that in the latter the mortars are 6 in. shorter and 3 in. narrower, which necessitates the stamps being closer together and less room for the ore to get from under the stamps. I find it a great disadvantage to the crushing capacity of the mill to have the ore brought to the mill very fine, for when the ore is fairly coarse the stamps have something hard to drop upon and the ore is pulverized much faster. This is something on the principle of the Gates rock-breaker; when the ore comes up from the mine as coarse as the jaws will take it, the capacity is much greater than when it is fed with fine ore.

ALEX CHALMERS.

Angels Camp, California, February 11.

Finger-Chute.

The Editor:

Sir—In your issue of October 17, 1908, appeared an article by Mr. T. A. Rickard, describing the finger-chute of the Alaska Treadwell mine.

Some years ago I saw the description of this gate by Mr. Kinzie and used the idea in the Liberty Bell mine at Telluride, Colorado. The excellent results secured under hard conditions seem to warrant a description of the gate as modified.

The Liberty Bell ore comes from the mine at a level 50 ft. above the floor of the loading-station of the aerial tramway. Dumped from the cars, it passes over grizzlies, the coarse and fine falling into separate bins. The coarse ore has a maximum drop of 30 ft. into the bottom of the bin when empty. The frame of the bin is of 12-in. square timbers, 5 ft. apart across the front. As originally constructed, the movement of all ore, coarse and fine alike, was controlled by ordinary stopper-boards reinforced with iron and held in slots in a subordinate frame-work between the main front posts. At no time was there difficulty with the fine ore, but the trouble in moving the coarse ore was continuous. With little ore in the bin, there was hard wear and breakage of boards and subordinate frame-work. As the ore accumulated, it arched between the floor and the above frame-work, requiring the effort of two men to supply 20 tons hourly to the tramway.

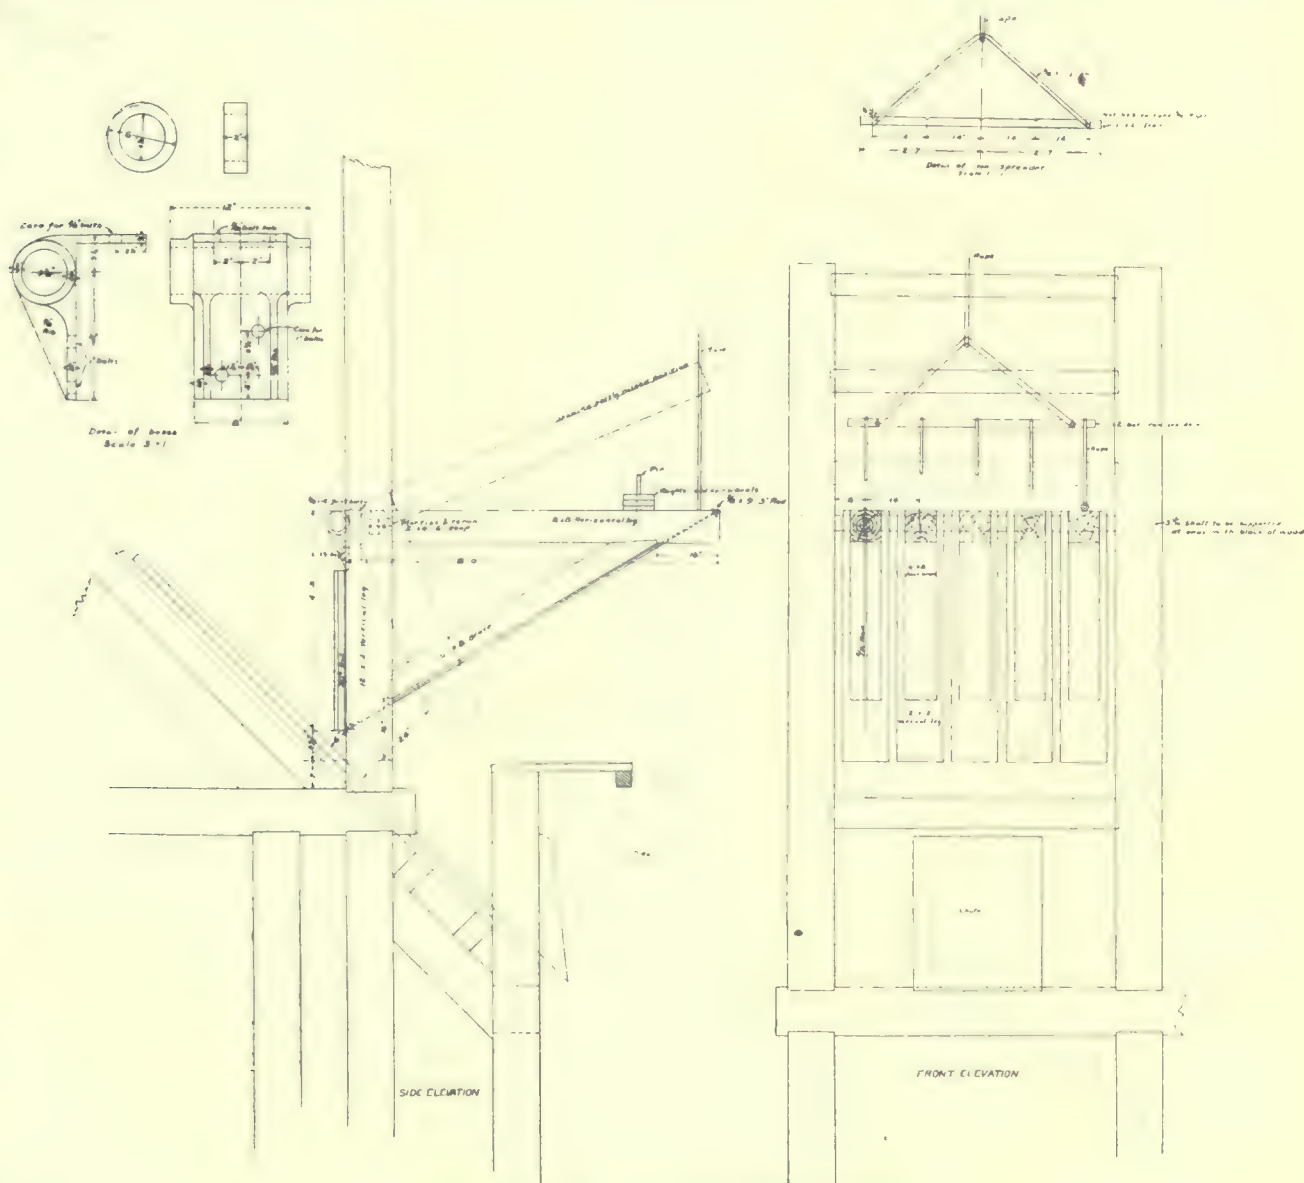

The finger-gate offered advantages even though it seemed to have been used against a constant pressure rather than to absorb the shock of flying ore. This condition seemed to demand weight in the fingers. The necessity for doing away with the tendency to arch seemed adequately provided by the length of finger given. Therefore we built our first

fingers as shown in the accompanying drawing: 12 in. square verticals, 8 in. square horizontals, and 6 by 8-in. braces. The verticals were faced with 30-lb. rail. The weights shown proved unnecessary. The equipment for raising the gate was the same as has been described.

The operation of the gate has been satisfactory, the repair costs have been low, and one man less per shift has been required. The gate is raised, the ore runs freely into our so-called fore-bay, in which it

crusher maintains a steady feed by pulling one or two ropes at a time. The rope-ends come down to convenient distance and no windlass is used. Both there and at the Liberty Bell the ore is wet at times and somewhat sticky.

In many places a simpler gate will serve, but for coarse ore when there is danger of arching and shock must be absorbed, the finger-gate has merit. Between the light finger, as built at the Alaska Treadwell, and the heavy one used at the Liberty Bell there

Finger-Chute Used in Liberty Bell Mine, Colorado.

lies without pressure, and from there through the simple hand-operated flap-gate into the one-third ton tramway-buckets.

So satisfactory has the gate been that it has been installed above the crushers in a new ore-house and underground in a large pocket. At these points it is likely that single-acting air-cylinders will be used to raise the fingers in order to expedite the movement of ore.

At the Mogul mill at Pluma, South Dakota, the dimensions used at the Alaska Treadwell have been followed in a gate placed above the crusher. The bin above is comparatively shallow. It seems that at this plant the fingers have separate ropes and the

crusher maintains a steady feed by pulling one or two ropes at a time. The rope-ends come down to convenient distance and no windlass is used. Both there and at the Liberty Bell the ore is wet at times and somewhat sticky.

Denver, February 4.

CHARLES A. CHASE.

The height to which a jet of water may be thrown in a vertical direction depends on several factors. The nozzle should be long and only slightly conically convergent. A greater height will be obtained with a large jet than with a smaller; thus, for instance, under a head of 300 ft. with a 6-in. jet, an elevation of 270 ft. may be reached, while with a 2- and a 1-in. jet, only 210 and 150 ft. respectively would be attained. In order to diminish resistance from the descending water a jet must be directed with a slight inclination from the vertical.

THE VACUUM-PUMP IN THE CYANIDING OF SAND.

By W. A. CALDECOTT.

*The use of the vacuum-pump in cyanidation is as old as the first introduction of the cyanide process in this district by J. S. MacArthur in 1890,[†] but of late years the method of vacuum-filtration generally has had far more attention paid to it than at any previous period. Various old sand-plants on the Rand were fitted with small vacuum-pumps connected with the leaching-vats, but this practice for some time past has not been general. At the joint Simmer Deep-Jupiter plant, which has ten 50-ft. sand-leaching vats, a large vacuum-pump with a capacity of 420 cu. ft. air per min. was installed, but being somewhat large has since been replaced by one of a quarter the size. The results proved so satisfactory that the practice will now be adopted at other plants, as the cost of installation and of power for operation is small. In installing a vacuum air-pump, it is connected with the upper portion of a receiver, while a plunger-pump for the solution is connected with the lower portion of the same vessel, or if the nature of the ground permit of it, a pipe from the bottom of the receiver may be carried down to dip below the solution-level in a small vat placed about 30 ft. lower. In the latter case solution entering the lower sump by the pipe from the receiver is re-elevated to the boxes by a centrifugal or other pump. No brass fittings should be employed in any of the above pumps.

Each leaching-pipe from the sand-vats is connected with the receiver by a short by-pass pipe fitted with a valve, but when leaching is proceeding freely, as in the earlier stages when the surface of the sand-charge is still covered with solution, the vacuum-pump is not used, and the full flow of solution under the action of gravity proceeds direct to the boxes. When, however, the rate of leaching falls off, the connection to the receiver is opened, and the air and solution-pumps are started. The former maintains a vacuum of say 10 in. of mercury, while the latter removes solution continuously from the receiver and delivers it to the boxes. This operation is continued for an hour or two after the charge is drained, so as to draw down air into all the interstitial spaces in a way which, owing to capillary attraction, is practically impossible in the usually limited time available for sand-treatment with leaching by gravity only. Such thorough draining and aeration is carried out three or four times during the treatment of a charge of sand, and with especial thoroughness prior to the discharge of the residue. By employing two receivers, strong as well as weak solution can be drained off simultaneously. Sand ready for discharge, and apparently drained thoroughly by gravitation-leaching, will on application of the vacuum-pump yield a strong flow of solution amounting to several tons per charge, of which the gold content

would otherwise have gone to the residue-dump.

The advantages derived from the foregoing practice are fairly apparent, but may be specified as follows: (a) The time required for the passage of a wash through the charge is much reduced; (b) owing to the small percentage of moisture, say 9%, left in the sand after each draining and aeration with the vacuum-pump, very little gold-bearing solution is left to mix with and raise the value of the next wash, so that the leachings are soon reduced to a minimum value, and a less volume of wash-solution effects a more thorough removal of dissolved gold than by the present usual practice; (c) the amount of moisture discharged with the residue is much reduced, and (d) the aeration obtainable during treatment accelerates the dissolving of the gold by supplying oxygen to the solvent.

Besides its use in the leaching-vats proper, a vacuum-pump is of obvious assistance in the speedy removal of water from a collected sand-charge, or of solution where sand is settled from a sand-solution pulp, so that the charge is the sooner ready for transfer, and the collecting capacity of a given number of vats is increased. In the use of the vacuum-pump in former times already referred to, the main object was to assist in the leaching of slimy and slow-leaching charges, but under these conditions the solution tended to travel in the path of least resistance, and the practical abandonment of the practice was probably due to the slight benefit afforded by small vacuum-pumps under such circumstances. At the present time, uniform freely leachable charges, free from slime in the interstitial spaces between the sand grains, yield the best results from the application of the vacuum-pump.

In the Miami copper mine, near Globe, Arizona, the ore in the upper workings of the property averaged about 3%. At the 400-ft. level the average was 2¾%, and at the 570-ft. level, the lowest in the mine, in the first drift from the shaft, the average was about 2½%. This steady decline in the copper content of the ore led to the belief that the bottom of the orebody was approaching, although all ores carrying 2% copper are workable. As the 570-ft. level development work progressed, however, the drifts have again run into high-grade ore. This would indicate that the fears of the Miami orebody pinching out were not well based, and that the tonnage of high-grade ore in the mine will be greater than heretofore assumed.

Manganiferous silver ores occur at Leadville, Colorado, in large deposits at or near the contact of porphyry and blue limestone, replacing the latter. These deposits consist of a black mixture of manganese and iron oxides with lead carbonate and silver. The manganese content varies from 10 to 40%. Manganese and iron oxides are associated only with the oxidized portions of the Leadville deposits. In the lower unoxidized portions the minerals are mainly pyrite, marcasite, sphalerite, and galena. Manganese minerals are conspicuously absent, and it is believed that the large quantity of manganese oxide in the unoxidized ore is due to infiltration from the porphyry.

CORNISH PUMPS AND PUMPING ENGINES.—II.

Written for the MINING AND SCIENTIFIC PRESS
By HENRY F. COLLINS.

The great advantage of the Cornish engine as compared with other types used for operating Cornish pumps is its simplicity and the small number of wearing parts. Reference has already been made to the long active life of many pumping-engines still at work, and it may be stated with confidence that no other type of engine can show such a record; this is due primarily to simplicity of design. The first cost of a Cornish engine is doubtless higher than that of a compound horizontal engine to do the same work, but against this we may offset: the annual cost of maintenance; double pitwork with balanced rods; extra cost of the quadrants for the horizontal engine, this last item being an offset against the cost of the beam for the Cornish engine.

When, however, the quantity of water to be raised through one shaft is greater than the capacity of one set of 24 in. pitwork, so that two sets have to be installed in the one shaft, the horizontal engine seems to be distinctly indicated. A case in point is the Tas-

Indicator Cards From Cornish Pumping Engine.

Working $4\frac{1}{3}$ strokes per min.; cylinder 90 in. diam.; cylinder-stroke 10 ft., pump-stroke 9 ft.; boiler-pressure 41 lb.; vacuum 8 to 10 lb.; cut-off $\frac{3}{8}$; mean pressure 22.31 lb.

mania mine, at Beaconsfield, Tasmania, where the new plant (which is capable of raising from a depth of 1000 ft. no less than 8,000,000 imperial gallons or 40,000 short tons of water per 24 hours) comprises three separate units, each of which consists of a compound horizontal engine with cylinders, 54 and 108 in. diam. by 10 ft. stroke, to which is attached by means of quadrants a pair of balanced rods tapering from 22 in. down to 18 in. sq., each working plungers of 20 in. diam., with steel rising mains that are, however, only 16 in. diameter.

As to the comparative economy of the compound-horizontal and Cornish types of engine no exact figures are available but it seems certain that the full economy theoretically obtainable from the use of steam at 150 to 160 lb. pressure can never be realized in practice on account of the fact that the initial velocity of the piston corresponding to so high an initial pressure would throw too heavy a strain upon the rods and quadrants.

Many attempts have been made at different times to compound the Cornish single-acting engine and thus secure the additional economy realizable from the expansion of steam from higher initial pressures. The first of these attempts was by Woolf in 1814 and a later and more notable one was that of Sims in 1840, the engine erected by this engineer at the Carn Brea mine in that year having a high-pressure cylin-

der 60 in. and a low-pressure cylinder 90 in. diam. Neither of these compound engines, however, did as well as the best of the simple engines working at the same time. A more recent attempt of the same kind is that of Davey, whose inverted compound single-acting engine with his valuable differential cataraet gear has been erected in one or two places. Again, however, the greater economy seems to be as elusive as ever, the advantages of expanding steam from an initial boiler-pressure of 150 lb. are obvious, in theory, but in practice they seem to prove unattainable.

The accompanying two sets of diagrams taken respectively off a 90 in. Cornish engine about 40 years old and an inverted compound single-acting engine

H.P. BOTTOM $\frac{1}{48}$
MEAN PRESSURE 44.5 LB.

H.P. TOP $\frac{1}{48}$
MEAN PRESSURE 4.95 LB.

L.P. TOP $\frac{1}{12}$
MEAN PRESSURE 3.85 LB.

DATE DEC. 3, 1908.

L.P. BOTTOM $\frac{1}{12}$
MEAN PRESSURE 5.75 LB. (VACUUM)

Indicator Cards From Compound Cornish Pumping Engine.

Working $3\frac{1}{4}$ strokes per min.; high-pressure cylinder 54 in. diam., 8-ft. stroke; low-pressure cylinder 94 in. diam., 10-ft. stroke; boiler-pressure 155 lb.; vacuum 17 to 22 lb.; cut-off $\frac{3}{8}$.

about 5 years old will illustrate the point. The plain Cornish engine is at the present time raising water from the 300 fathom or 1800 ft. level in the Wheal Agar vertical shaft of the East Pool mine by means of 8 plunger-lifts 16 to 16 $\frac{1}{2}$ in. diam. with a short 15 in. bucket-lift at bottom. The water load in the shaft is 142,196 lb., equivalent to 20.11 lb. per sq. in. on the piston, while the stroke of the rod is 9 ft. Neglecting friction and slip, therefore, the theoretical water hp. at $4\frac{1}{3}$ strokes per min. would be 168.04, whereas the indicated horse-power is 186.372, the 'efficiency' shown being thus 90.16%. The consumption of coal being about 5 tons per 24 hr. the calculated 'duty' or number of foot-pounds supposed to be done in raising water per 112 lb. of coal used, neglecting slip and friction, is about 79 millions. Coal is never

weighed into boilers at Cornish mines, so that the fuel consumption is never known exactly except as an average over a considerable period of time, still the above figure is pretty close to the truth. As to the actual water horse-power no figures are available because the water raised is never measured; this would be the only means of determining with accuracy the slip. Still it may be reckoned that 20% is an ample allowance for slip and friction together, and in any case the calculated duty will serve as a fair basis for comparing the work done by different types of engine.

Turning now to the diagrams of the compound single-acting engine, it may be remarked that this engine is by the firm of Hathorn, Davey & Co. and is working at the mine in Spain already mentioned. It operates a fine set of pitwork put in during the past few years with an 18 in. plunger at 557 ft. from surface or 590 ft. below the level of the discharge from the 16 in. rising main; the second plunger at 951 ft. from surface, or 394 ft. below the first, is 18½ in. diam.; a third temporary plunger of the same diameter is at 1150 ft. from surface or 200 ft. lower, while below this again is an 18½ in. bucket-lift. When the diagrams were taken the latter was unhitched, at which time the total theoretical water-load per stroke in the shaft was 1,301,068 ft. lb. which at 3¼ strokes per min. (the dry-season rate) is equivalent to 128.14 calculated water horse-power. The indicated horse-power developed by the engine on the active or 'indoor' stroke is calculated thus:

	Mean pressure of steam.	Area of piston (sq. in.) × stroke (ft.) ÷ 33,000.	I. H. P.
High-pressure bottom	44.50	0.540	78.10
High-pressure top	4.95	0.555	8.88
Low-pressure top	3.85	2.103	24.95
Low-pressure bottom	5.75	2.087	38.82
			150.75

The efficiency, that is $\frac{\text{I. H. P.}}{\text{calculated water hp.}}$ is in this case, therefore, only 85.6% as compared with 90.16% in the Cornish simple engine quoted. The lower efficiency seems at first sight inexplicable yet some light can be thrown upon it, as will be seen later. The consumption of coal in this engine has been several times determined by careful tests lasting a week each, the evaporative power of the coal has been also ascertained at the same time by careful measurement of the feed-water used. Careful consideration of the prices of the various kinds of fuel obtainable locally, after many experiments, has dictated the use of a mixture of two parts of steam coal with one part of anthracite slack, the latter being so very much cheaper as to more than offset its inferior quality. The net realized evaporative power of the mixture averages 7.79 lb. and calculation of the volume of the steam entering the cylinder before the cut-off operates, checks fairly with the actual weighed consumption of coal, which at this comparatively slow speed works out at 2.296 lb. per stroke or 2.97 lb. per I. H. P. per hr., equivalent to just under 2½ lb. per I. H. P. hr., using coal having a realizable evaporative power of 9, or 2.97 lb. per I. H. P. hr. with coal having a realiz-

able evaporative power of about 8.5. The calculated duty therefore, neglecting slip and friction is about 63,500,000 ft. lb. per 112 lb. coal burned—equivalent to about 69,500,000 if the coal burned had, like that consumed by the Cornish engine, a net evaporative power of about 8.5.

We are therefore brought face to face with the remarkable fact that whereas an old single-acting and single-expansion Cornish engine using steam at 41 lb. pressure shows a calculated duty of 79 millions, a quite new compound single-acting engine, doing similar work under similar conditions but using steam at 155 lb. pressure, shows a duty of 69½ millions when using a similar quality of coal. The result would be startling if we were not aware of previous failures of slow-moving compound engines to realize in practice the expected economies. No complete explanation can be afforded of the comparatively poor economic results shown by this particular compound engine, but the following considerations may throw some light upon it: (1) The initial pressure in the high-pressure cylinder with the stop-valve wide open is seen from the diagram to be only 87½ lb., whereas the boiler-pressure was 155 lb. and the pressure in the steam-pipe just behind the stop-valve was from 145 to 150 lb. during admission. This proves either that an enormous amount of condensation was taking place in the high-pressure cylinder or else, as is more probable, there was a large amount of 'wire-drawing' through the admission-valve and passages. The cylinder being jacketed and not very hot to the touch it is probable that the falling off in initial pressure in the cylinder as compared with the pressure in the steam-pipes is due chiefly to wire-drawing through the stop and admission-valves and passages. (2) The lower efficiency, that is, $\frac{\text{I. H. P.}}{\text{calculated water horse-power}}$, of the compound engine as compared with the simple Cornish engine, namely, 90.16% as against 85.6%, is probably due to the fact that the radiation losses in an engine making only 3 to 5 double strokes per minute are of much greater moment than in ordinary swiftly moving compound engines. Under these exceptional conditions of slow motion with long periods of rest, the total radiation from the two cylinders and the long steam-pipe reservoir between them forms an appreciable fraction of the total heat; expansion by stages under these conditions becomes actually less effective than direct expansion to the limit in a single cylinder. (3) Even if the valves and passages were enlarged so that the initial pressure inside the high-pressure cylinder could be raised to something approaching the boiler-pressure, say 120 to 130 lb. per sq. in., cutting off earlier in the stroke, it seems probable that the shock to the pitwork from the consequently much higher initial velocity of the piston would be so great that from motives of prudence the stop-valve would have to be kept partly closed, with the result that the steam would be wire-drawn to exactly the same extent as now obtains, with the restricted passages of the present admission-valves.

Although, at present, I am unable to cite similar exact details of practice with compound horizontal

engines operating Cornish pitwork, such information as is available to me indicates that the same difficulties have been experienced and that they fail in practice to realize the economies in fuel consumption theoretically attainable, in exactly the same manner as the vertical compound engine cited has failed to realize those economies. The other advantages offered by horizontal engines, namely, compactness and low cost of engine-foundations and house for a given pumping capacity, still subsist, and for a very large quantity to be raised from a single shaft (anything more than 1,500,000 to 1,700,000 gal. per 24 hr., which is the limit for a single set of pitwork, as stated at the beginning of this article) there can be no doubt that the horizontal engine with balanced double pitwork is not only the cheapest, but the most convenient in working. If on the other hand the quantity of water to be handled is within the capacity of a single set of 18 or 20 in. pitwork, no type of engine will give more reliable service, or work with greater economy than a plain well-built single-acting Cornish engine using dry steam at a boiler-pressure of about 45 to 50 lb. and maintaining a good vacuum. For intermediate conditions, that is, for quantities of between 1,200,000 and 1,700,000 imperial gallons per 24 hours, the choice as between a Cornish engine with single 24-in. pitwork and a horizontal engine with double 18 or 20 in. work is one that should be decided by circumstances, such as the probability or otherwise of an increase in the water, and by local conditions such as facility of transport, of obtaining good building stone, etc. For what may be called frontier conditions, such as prevail in the newer and less accessible mining camps of the Western States and Mexico, both Cornish pitwork and the engines required for working it are alike unsuitable solely on account of the great weight of the installation, which would render both transport and erection excessively costly. But in the Eastern States and even in the older and more settled mining camps of the Western States, such as Butte and Leadville, it may be doubted whether sufficient attention has been given to the advantages of the Cornish system of pumping, which are certainly worthy of more careful consideration than they have hitherto received at the hands of American mining engineers.

Dust clouds are not infrequently blown over the Mediterranean from the sandy plains and dessicated pools of north Africa. When in moderate quantity this southern wind is known in southern France as the 'Sirocco'. Often, however, the quantity is enormous. In the middle of the 18th century an area of north Italy, estimated at about 1800 square miles, was covered with a layer of dust which in some places reached the depth of 1 inch. In 1846 the Sahara dust reached Lyons, and it is said to have since been detected as far as Boulogne, in the north of France. A most remarkable example occurred in March 1901, when a vast amount of dust was carried from the desert south of Algeria across Europe into Russia. It is estimated that not less than 1,800,000 tons of fine sand and dust were then transported, two thirds of which fell south of the Alps.

CONFLICT OF PLACER WITH QUARTZ CLAIM.

A **placer claim** was located in 1892, and in 1898 a quartz location was made by other parties, the boundaries of which conflicted with those of the placer claim. The quartz locator applied for and obtained a patent for his claim in 1905, which application and patent included the area in conflict with the placer. The placer claimant failed to adverse the quartz patent application. Since issuance of the patent, it has been determined that the pay-channel of the placer crosses underneath the surface and passes through the vertical boundaries of the quartz claim. The enquiry is, has the placer claimant the right to follow

the channel underneath the patented quartz claim? The answer is obvious. He has no such right. Having failed to adverse the application for quartz patent, the placer claimant waived whatever rights he might have had by virtue of priority of location. The quartz patentee is conclusively presumed to own the entire surface and everything within the vertical boundary planes of his patented claim, except as against one having the apex of a lode in a location outside of the patented quartz claim boundaries, such outside apex locator having the right, under certain conditions, to follow his vein on its downward course underneath the patented surface. No such right is given to the owner of a placer claim to follow his pay-channel underneath patented claims. The fact that the quartz mine can not be profitably operated is not an element to be considered. Such fact subtracts nothing from the rights conveyed by the patent and adds nothing to the rights of the placer claimant.

Rhodochrosite is principally found in ore bearing veins, and although more commonly found in silver veins, it is also present in gold veins, being particularly abundant in the Telluride district, Colorado. It usually occurs in brilliant pink bands running longitudinally in the vein.

CONCRETE IN MINE SUPPORT.

Written for the MINING AND SCIENTIFIC PRESS
By W. R. CRANE.

With the constantly increasing difficulty experienced in securing sufficient quantities of the proper kinds of timber for use in mines, and with prospect of still greater scarcity, a demand has come for a suitable substitute for timber in mines. Concrete seems to be best suited, owing to its adaptability. At present concrete is receiving extended application, and owing to many successful substitutions for timber under severe conditions, it is growing in favor.

Other materials used in place of timber in mines are stone and brick, but these have not met with favor in American practice, primarily because of the high cost of transportation and also perviousness. Concrete enjoys the advantage over stone and brick in that it can be more readily placed; as fewer skilled laborers are required, the first cost is likely to be considerably less, but it takes about three times longer to place concrete than to set timbers, and from actual experience it has been shown that concrete exceeds timber in first cost from 25 to 45%, the variation depending largely upon the shape of the construction. When once constructed, however, a concrete lining is practically indestructible, and few or no repairs are ever necessary, hence no delays, with consequent loss of output and extra expense of maintenance result.

Another important factor is the great strength of concrete as compared with timber; this is especially true of shaft-lining. Concrete is now widely employed in lining shafts and mine galleries, tunnels, gangways, in the support of rooms and stations, in building dams and stoppings underground, and so forth.

It has been found that the shape of a shaft-lining is not of as much importance, from the standpoint of support, as was formerly thought. Circular and elliptical forms are necessary when stone and brick are used, and are obviously to be preferred when concrete blocks are employed. Several rectangular concrete shaft-linings have been successfully constructed in the United States, but practice favors oval and elliptical forms. Strength and cheapness are the principal reasons for the choice of circular and elliptical forms; but these are not economical of space. However, only about half the thickness of lining is necessary when curvilinear forms are employed; therefore the size of the excavation is actually reduced, and the cost of the concrete lining is practically halved.

In tunnel-work two or more lines of track necessitate an arched roof, while with one line of track, the lining may be rectangular or oval, with the longer dimension usually standing vertically. In the former case the sub-divisions or compartments are usually separated one from the other by longitudinal partitions of concrete, or simply by steel posts, while in many instances the two forms are combined, giving an exceedingly strong reinforced concrete construction.

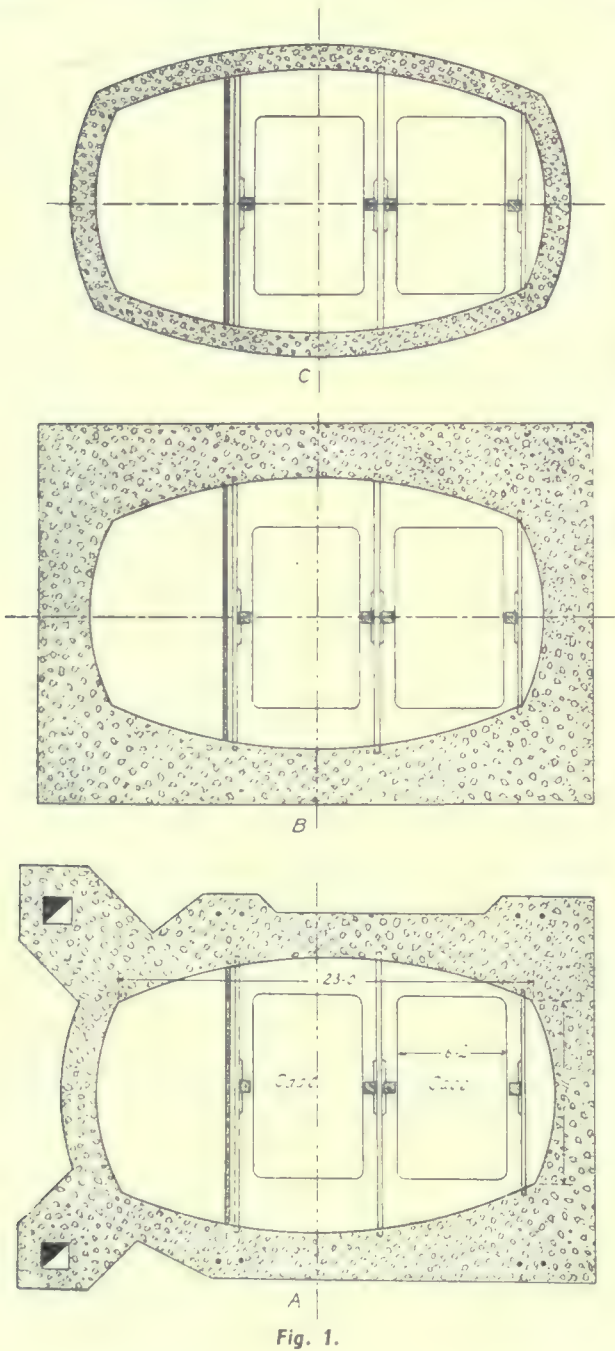

Probably the most extensive linings for steeply inclined shafts are to be found in the Lake Superior copper region, on Keweenaw Point, where the shafts are usually sunk on lodes that dip from 35 to 80° from the horizontal. These shafts, for the larger mines, have two hoisting compartments and a man-way, and therefore require an arched lining extending from the surface through 40 to 80 ft. of glacial drift, composed of sand, gravel, and boulders, down to bedrock. This detritus is water-bearing, which condition increases the difficulties of construction. The lining is carefully connected with the bedrock, drainage-holes being provided through which the excess of water can escape, thus maintaining a low head and reducing the danger of disturbing the concrete. Other important constructions of concrete and reinforced concrete, are shaft and pump-stations, which are now being widely employed in both coal and metal mines. Aside from the stations mentioned, special rooms, such as underground offices, hospitals, lamp-rooms, and stables are now being built of concrete. Lining, and the re-lining, of gangways, formerly timbered, with brick and concrete is the usual practice in the large mines of the United States. This is especially true of the Eastern coal mines, but also applies to many metal mines. Water and air-stoppings are now largely constructed of concrete, where permanency is desired. Ditches also, both in the mine and at the surface, are being made of concrete, having the advantage of durability and neatness in appearance.

Two elliptical shafts were sunk, and lined with concrete, on properties of the United States Steel Corporation, one being at Tug River, West Virginia, the other at Bridgeport, Pennsylvania. The coal department of the Lackawanna railroad re-lined at least four shafts in collieries belonging to that company in the vicinity of Scranton, Pennsylvania. These linings were of reinforced concrete, rectangular in section. They passed through 60 to 75 ft. of 'wash,' connecting the surface with bedrock. The elliptical shaft-lining at Bridgeport is 23 by 15 ft., inside measurement. The 81 ft. of lining was varied with depth, having three sections, as shown in Fig. 1, C being the lower section, B the middle section, and A the upper section or tippie foundation. This was put down as a sinking-lining or drop-shaft, being provided with a heavy timber shoe, with an angle-iron cutting-edge. The dimensions of the shoe corresponded to the middle section of the shaft-lining, B, being in fact the only portion that was a drop-shaft. Some 30 ft. of forms for the reception of concrete were built upon the shoe, after it had been leveled in the initial excavation, and the concrete placed, smoothing was done by running a long-bladed shovel up and down next to the inner form. Ten days were allowed for the setting of the concrete, after which the outside members of the forms were removed. Settlement of the lining was accomplished and controlled, in the usual manner, by evenly removing material from beneath the shoe, which method was continued until the shoe came to rest upon a hard shale, which capped the coal. About 5 ft. lower a

foundation-ring was cut, and a shell of concrete was built to the sinking-lining above, thus completing the middle section of the shaft-lining. The shaft was then sunk through the coal stratum to a point 10 ft. below it. This portion of the shaft was then lined with concrete, having the section shown at C, Fig. 1, but having, in that part contiguous to the coal stratum, openings provided for gangway connections. The upper portion of the lining was then

of 8 by 12-in. angle-buntions into the concrete walls, holes being chiseled for their reception, and when placed fresh concrete was rammed around them. This method of placing buntions has proved most satisfactory. An attempt at Tug River to use cast-iron buntion-pockets was abandoned owing to excessive leakage around them.

Probably one of the best illustrations of re-lining a timbered working is that of the Manville shaft, in the vicinity of Scranton. The lining is rectangular, and the partitions dividing the shaft into compartments were broken up into buntions by large oval openings

built, constituting the capping of the lining, also serving as a foundation for the tippie. (See A, Fig. 1.) Seepage of water was prevented during construction by placing strips of canvas against the rock-walls and filling the space between them and the forms with concrete. As a further precaution, iron pipes, 1 to 2 in. diam., were laid in the concrete, permitting the escape of percolating water. Subsequently, when the concrete had set, caps were screwed upon the pipes, checking the flow of water. When the lining was completed the shaft was divided into three compartments by setting three lines

Fig. 2.

Fig. 3.

being left in them. Expanded metal and rods were used in connection with the concrete, thus reinforcing the comparatively thin walls. For details of the construction the reader is referred to No. 31 in the bibliography.

The Syracuse shaft on the Mesabi range is an excellent example of the use of a variety of methods to overcome difficult conditions in sinking; the final and successful completion of the work being largely due to the use of reinforced concrete. See reference No. 25.

Recently the Bangor shaft was sunk through

quick-sand at Biwabik, on the Mesabi range. The work was accomplished by a concrete drop-shaft, and while the use of drop-shafts is neither new nor unusual, the successful employment of reinforced concrete in this connection is somewhat of an innovation in American mining practice. As usual, a steel shoe served as the foundation of the superstructure of concrete, upon which two forms were built; an inner one of 14 ft. 6 in., and an outer one of 22 ft. 6 in., thus leaving a clear annular space of 4 ft. between the two retaining walls of the forms, which is the thickness of the shaft-lining. No attempt was made to free the shaft of water during the process of excavation, the sand being removed by dredges of the clam-shell and orange-peel types. To facilitate the use of the dredges and to control the movement of the drop-shaft, a steel cylinder 6 ft. diam. was built of flanged sections 8 ft. long, bolted together at the flanges. As the drop-shaft settled, the concrete was built up in lengths of 8 ft., reinforcing rods of high-carbon steel being set into the concrete near the outer form, also staggered somewhat to increase the area of reinforcement. The rods were looped at the ends in order that other rods might be attached as the lining increased in height. When necessary to do work at the bottom of the shaft, the water could be forced out of the inner metal cylinder by compressed air, in a manner similar to that employed in caissons, airlocks being established in the tube.

The substitution of concrete for timber in the support of drifts and gangways is well illustrated by the practice in the mines of the Philadelphia & Reading Coal & Iron Co., near Shamokin, Pennsylvania. Here concrete arches and columns for the support of the roof, where long spans are necessary, are successfully employed, and their use with similar applications is extending rapidly. The concrete arches take the place of timber sets composed of 14 to 16-in. posts and caps, lagged with 4 to 6-in. round timber, and spaced at intervals of 5 ft., centre to centre. The concrete forms were placed close to the old sets, and were built of 1 by 8-in. boards, and provided with 2 by 6-in. braces. The first arches made were 24 in. square, in sections, while the later ones are only 18 in. square. The earlier forms were reinforced by old 25-lb. rails, two being placed side by side, lying about 3 in. from the sides in the inner corners. These rails were bent to conform somewhat to the shape of the arch. In the arches last built old wire rope was used instead of the rails, being woven back and forth through the concrete. After about two weeks the forms were removed and the arches were complete. That the arches are sufficiently strong is shown by the fact that not the slightest check has occurred in any of them. The cost is approximately \$27 and \$22, respectively, for the 24 and 18-in. sizes. (See Fig 2.)

Triangular columns are occasionally built at certain points as, for example, where three roadways meet, leaving a large triangular space, which in many cases is much too wide for an unsupported roof, and as it is quite important that no settlement should take place, wooden cribs filled with rock or timber-supports are unsatisfactory. Concrete has

been used successfully at such points, and could be used to advantage in supporting the roof at sharp corners where a road is turned from the main gangway at a small angle. (Fig. 3.) Underground stations, such as those in which pumps are placed, are now being lined and supported by concrete. (Fig. 4 and 5.)

The preservation of mine timber has been under consideration in many districts, especially in the coal mines of Pennsylvania, and has led to the establishment of a number of plants for the treatment of timber. It is interesting to note, however, that at least one large company, the Reading, has been experimenting with concrete props, which have proved so successful that it is proposed to build a plant at the North Franklin colliery, where such props will be manufactured for distribution to neighboring properties. This movement augurs well for the future of concrete in mines.

A possible and extremely practicable application of concrete is in the support of weak roofs during the extraction of coal. This use of concrete has hardly been more than tried in the United States, but is widely employed in Europe, especially in Burgundy, where thick coal-seams are worked in benches. Each bench, when the one above is excavated, is covered with a bed of concrete 8 to 10 in. thick. Being placed 12 to 14 in. below the level of the bench, this serves as a support for the tracks. The concrete is placed in sections transversely to the working face, good connection between the successive sections being ensured by leaving a feather-edge on the advancing side. Upon this bed of concrete is placed the filling with which the excavation is stowed on the removal of the coal, and by it the filling is supported while the next bench is being excavated.

As the maintenance of air currents in coal mines is so important, concrete offers great advantages. Probably no portion of the air-ways should be constructed with greater care than the 'over-casts,' and for that reason concrete is being used. Such use of concrete is shown in the coal mines at Flat Top, Alabama. See reference No. 22. The Lehigh Valley Coal Co. is substituting reinforced concrete for wood and stone 'over-casts' in the Wyoming coal region of Pennsylvania; at least four such constructions are employed in the Dorrance colliery. For the details, reference No. 23 may be consulted. Next in importance to over-casts in mine ventilation are 'air-stoppings.' The problem of ensuring brattices and stoppings against danger from explosions of gas or coal-dust has been solved by the employment of concrete. A wall of concrete is built across an air-passage at the desired point, being set into the walls, roof, and floor to a sufficient depth to prevent leakage of gas or air, and to give adequate strength. Occasionally an opening is left in the stopping, which is further provided with a canvas or wooden door, this being known as a 'brattice explosion-door.' The door is usually placed at such a height, and is of such size, that men can readily pass through, and will permit a large volume of gas or air to pass, should an explosion break it down, thus relieving the fan

from undue pressure, which might otherwise damage or demolish it. Where air-stoppings can be placed in abandoned or little-used passages, and where such stoppings are so situated that their effect in checking the force of explosions will not result in damage to the fan, air-tight constructions may be employed. The use of concrete in such work is now common practice, and as light construction is most desirable, reinforced concrete is usually employed. The reinforced concrete stoppings at the Flat Top mine in the Birmingham district, Alabama, may be taken as typical of such work. In order to ensure a good contact between the walls and the concrete, so as to

heads are placed in the adit at points 100 ft. or more back from the intersections of passages employed in skirting caved ground. The Ontario adit has a rock-section 5 by 7 ft., and as the bulkheads are 12 ft. square in the vertical plane, the walls must be recessed to a depth of 3½ ft. on the sides and 2½ ft. on the top and bottom. The bulkheads are 9 ft. thick, and have, therefore, a comparatively large

Fig. 4.

Fig. 5.

prevent leakage of air, the walls, roof, and floor are carefully dressed and recessed to a depth of several inches. Wire netting of about 2-in. mesh is stretched across the opening, which, with the recessing, may be made as much as 10 ft. square, and fastened temporarily by iron pins driven into the walls. Two widths of netting are usually employed, of such width as to overlap a foot or more in the middle. A form is then erected on either side and the concrete placed, being carefully rammed, especially around the walls. The usual thickness of such stoppings is 8 inches.

As a protection to miners and workings, bulkheads are often built in gangways and tunnels. The reinforced concrete bulkheads recently erected in the main Ontario adit, which was driven as an extension into the property of the Daly-West mine, at Park City, Utah, are excellent examples. These bulk-

Fig. 6.

superficial area, parallel with the tunnel. In the centre of the bulkheads is an opening 4 by 5 ft., in the clear, to serve as a doorway for the passage of men, cars, etc. The door is of reinforced concrete, consisting of ¾-in. plates and 10-in. I-beams, securely bolted together, the latter standing vertically, facing the workings. The plates being bolted to the flanges of the I-beams, that portion to which the hinges are attached consisting of double thickness, made by two plates. The spaces between the plates and I-beams are filled with concrete, thus making an extremely strong and impervious construction. As a precautionary measure, forty 3-in. pipes, provided with valves, are set into the concrete, forming a double row of openings approximately paralleling the sides and top of the doorway, by means of which the pressure upon the bulkhead may be increased or relieved at will. (See Fig. 6.)

The use of concrete in intercepting ditch construction is shown to good advantage in the water-rings used at the Phillips plant of the H. C. Frick Coke Co. of Fayette county, Pennsylvania. (See Fig. 7.) One of the first uses to which concrete was put was that of building foundations for heavy machinery, engines, pumps, compressors, and reducing machinery, etc., its use not being confined to the surface only. Retaining walls of concrete for the support of fills, as when site for buildings must be partly excavated and partly filled or built up, are now of common occurrence. These should be provided with drainage holes. Retaining walls are preferably built in vertical sections or panels, each panel being a day's work; this eliminates horizontal joints. Panels should be built alternately, the intermediate spaces being filled afterward.

An important use to which concrete has been put is in the support of tracks. Large longitudinal stringers are built; upon these the rails are mounted and to these they are securely bolted. Such concrete stringers are in use at the Ahmeek, Mohawk, and other mines in the vicinity of Calumet, Michigan. In Fig. 8 is shown a section of the shaft and a transverse section of a concrete stringer, encased in the mold, as may be seen at the Ahmeek mine. Preparatory to placing the stringers, the foot-wall or floor of the shaft is cleared of loose material and the mold-boards placed. Before filling the concrete, the space between the walls of the mold is flushed to bedrock, ensuring a clean face for the concrete. Through the centre of the stringer runs an old wire rope $1\frac{1}{8}$ in. diam., which has proved to be ample as reinforcement. Such concrete stringers have been in use in the Ahmeek mine for four or five years, being entirely satisfactory. This work was done under the superintendence of W. J. Uren.

A further extension in the use of concrete in and about mines is its employment in the construction of powder magazines. Underground magazines are as a rule simple in construction, consisting as they do, in most instances, of blind drifts or old stopes, walled off from the rest of the workings, and equipped with thawing racks and steam pipes. The concrete partitions are provided with iron doors and ventilating flues, while the floor of the magazine is of concrete, in which are drainage ditches leading through the partition. The heavy iron doors are securely locked. Powder magazines for the storage of explosives on the surface must have larger capacity, and are often built of concrete. The magazine of the Doe Run Mining Co. at Flat River, Missouri, is shown in Fig. 9.

An application of concrete employed in Europe, and that might be adopted with advantage in the United States, is in the form of reinforced plates or slabs for shaft-lining. Such plates have been successfully used at the Koenig colliery, in the Saar district, Germany. Blocks $9\frac{1}{2}$ in. thick, and of a length equal to the longer dimension of the shaft-section, are reinforced by $\frac{5}{8}$ -in. iron rods spaced from 2 to 4 in. apart, and running longitudinally through the plates. They are still further reinforced by 6-in. ribs, two to a plate, and built on the side opposite the

inside of the shaft. When in place the corners are strengthened by angle-irons, 2 by 2 in., which, with additional rods placed in regular order about the shaft, give ample support for the preliminary operation of lining. Finally, concrete is rammed between the plates and the walls, uniting the plates with the rock. The plates then serve the double purpose of a form and a finished wall, both simplifying and cheapening the operation.

Tungsten in ores may be determined as follows, according to Ekeley and Kendall (*Mining Journal*, Feb. 22, 1908): The ore is decomposed in the usual manner by digestion with aqua regia in a flask. After diluting and decanting through a filter, the residue is washed repeatedly with a 5% solution of NaCl until the washings show no acidity when tested with ethylamine solution and phenolphthalein. Allow as little as possible of the WO_3 or insoluble residue to get onto the filter. When washed, the filter is put into the flask, disintegrated, and a sufficient excess of standard ethylamine solution added. The flask is

standard oxalic (2.8 gm. per litre) and phenolphthalein indicator. The amount of ethylamine which has been neutralized by the WO_3 serves as a basis for the

Fig. 7.

Fig. 8.

stoppered and allowed to stand in the cold, with occasional shaking, until solution of the WO_3 has been effected. The solution is then titrated back with

calculation. The ethylamine solution is made by using 6 gm. of a 33.3% alcoholic solution of the base in one litre. 1 c.c. equals about 0.005 WO_3 .

OVERFLOW FROM DREDGE PITS AT OROVILLE.

There has recently been much discussion as to whether the colored water flowing into the Feather river from the tailing piles of the dredges could have an injurious effect upon the river. In an effort to obtain exact information upon this point, six samples were taken on November 29 by interested parties. The samples were as follows:

No. 1. Outflow from under the tailing piles at the bank of the river, near Gold Run, discharging about 10 miners' inches.

No. 2. About 100 yd. downstream from No. 1, opposite a big riffle in the river, about 40 miners' inches flowing out from the cobble piles.

No. 3. Water crossing from the east of the Marysville road into the tailing piles to the west, near the dam in the ditch east of the road and just south of the bridge crossing Gold Run.

No. 4. Outflow from the pit of a dredge, about 15 miners' inches.

No. 5. From above the dam in a dredge pit.

No. 6. Outflow from the pit of a dredge.

These samples were sent to a well-known assayer in San Francisco, with instructions to determine the foreign matter in grains per gallon, and also to ascertain the fineness of this suspended matter.

His report states that each sample was mixed by careful shaking and one litre drawn off. This was evaporated to dryness, and the weight of the total solids determined, as follows:

Mark.	Grains per U. S. wine gal. of 58,415 gr.	Per cent by weight.
1.....	187.783	0.32
2.....	215.772	0.37
3.....	274.092	0.46
4.....	753.468	1.29
5.....	2029.466	3.47
6.....	1014.733	1.73

Experiments were then made to determine the fineness of the suspended matter in the water. In the case of each sample all of this matter passed through a 200-mesh screen. The suspended matter consisted of silt of the finest grade. The solids shown in the above table included the solids in solution, which are always present in river water. To determine these latter, two samples of the clear river water were taken and their solids determined to be 8.854 gr. per gal., equal to 0.0151%. These amounts deducted from the corresponding items in the table leave the true amount of suspended matter in the waters under consideration, as shown in the following table:

No.	Grains per U. S. wine gal. of 58,415 gr.	Per cent by weight.	Solids in solu- tion, gr. per gal.	Net suspended matter, gr. per gal.	Per cent sus- pended matter.
1.....	187.783	0.32	8.854	178.929	0.305
2.....	215.772	0.37	8.854	206.918	0.355
3.....	274.092	0.46	8.854	265.238	0.445
4.....	753.468	1.29	8.854	744.614	1.275
5.....	2029.466	3.47	8.854	2020.612	3.455
6.....	1014.733	1.73	8.854	1005.879	1.715

For the purpose of determining the size of the particles, a microscopical examination of the sediment was next made. Slides were prepared by evaporating small portions of each sample to dryness and measur-

ing the sediment both with a stage micrometer and with an eye-piece micrometer. Under the microscope the sediment is seen to consist of an infinite number of particles of approximately the same size. These particles show a tendency to cake on drying, but under a strong light it was possible to see the individual pieces, and to measure them with a fair degree of accuracy. The particles in both samples vary in size from one one-hundredth to one four-hundredth of a millimetre. These dimensions reduced to decimals of an inch are respectively 0.0003937 and 0.0000984 in. The coarsest particles of suspended matter in the discolored water flowing into the river (samples 1 and 2) were only about 1/10 the size of flour particles, and the finest but 1/40 of that size. The material escaping into the river on November 29 contained from 0.30 to 0.35% of this extremely fine powder, or from 178 to 209 gr. per gal. The reports of the United States Geological Survey on 'The Surface Water Supply of California, 1906', show the flow of the Feather river on the dates specified (page 120), stated in miners' inches, to have been:

Date.	Flow, second-feet.	Miners' inches.
February 16, 1906.....	11,500	460,000
February 28	19,600	784,000
March 15	18,400	736,000
March 22	23,000	920,000
March 25	48,600	1,944,000
April 11	18,400	736,000
April 16	18,100	724,000
April 25	17,000	680,000
April 25	16,600	664,000
May 2	18,800	752,000
May 11	22,100	884,000
May 17	12,000	504,000
July 6	7,190	287,600
July 26	2,860	74,400
September 5	1,760	70,400
October 12	1,620	64,800
November 1	1,610	64,400
December 10	3,270	130,800

Such extremely fine material would not settle in a stream having a velocity of 2 miles per hour. As a matter of fact, material so finely divided does not settle short of tide-water. The bed of the river-channel consists of sand as far down-stream as Suisun bay. It is interesting to note that the river is scouring its channel deeper, from Sacramento down as far as the surveys in progress by the Engineering Corps of the United States Army have extended, which is about 14 miles. The same phenomenon is reported by the survey corps at Marysville.

Volcanic action has been considered to be caused by a development of heat resulting from radioactivity in limited tracts, at a depth of one to three miles from the surface, which may sometimes be sufficient to melt the rocks affected by it. The melting is gradual, and when a sufficient quantity is melted, the water which it contains becomes explosive and usually suffices to break through the covering, constituting an eruption. When all the lava is erupted, and the reservoir is exhausted, it closes up for a time. If the heat continues to be generated, more lava is melted, and in due time another eruption occurs.

TREATMENT OF THE GOLD AND SILVER
PRECIPITATE AT DOS ESTRELLAS.

Written for the MINING AND SCIENTIFIC PRESS
By WALTER NEAL.

At the clean-up in the Dos Estrellas mill, El Oro, Mexico, the gold and silver slime flows by gravity through launders from the zinc-boxes, first onto a 20-mesh screen, next to a 60-mesh screen, and thence to the first of two cement sumps. The short-zinc resting on the 20-mesh screen is returned to the head compartment of the zinc-boxes after being thoroughly washed: that passing 20-mesh and resting on 60-mesh is dried and melted, without acid treatment. From the first sump above mentioned the slime overflows to a second, whence it is pumped to the filter presses by a triplex plunger-pump. The idea of using two sumps is to hold back the greater part of the slime in the first, thereby enabling the pump to be run at full speed till work on the boxes is finished, and the zinc-room man can give more attention to the press. Then while the sumps are being pumped out, short-zinc is washed and the launders cleaned. Lastly the heavy sludge in the first sump is pumped out, and the sumps thoroughly washed.

After the clean-up is completed the precipitate is partly dried by passing compressed air through the cakes in the press. The press is then discharged into a movable steam-jacketed drying car which is run under the press to receive the cakes, then returned to its place, and connected to the steam line, the cakes being left to dry all night. A small vertical boiler is used for generating steam for this purpose, and is fired for about two hours, the fire then being 'banked' and the steam allowed to drop slowly. The cakes are melted the succeeding day; they contain only about 18% moisture. Until recently the precipitate was briquetted after fluxing, but this has been discontinued on account of the amount of handling involved. At the present time the precipitate is handled only twice, as against six times in briquetting, as follows:

Briquetting.

- 1. Cakes knocked from filter-frames to drying-car; and the car wheeled to place and steam connected.
- 2. Cakes shoveled from drying-car to fluxing-boxes; weighed; and fluxes added.
- 3. Mixed with shovel in boxes; and boxes wheeled to briquetting-machine.
- 4. Precipitate shoveled from boxes to hopper of briquetting-machine.
- 5. Briquettes lifted from briquetting-machine by hand and placed in boxes; and run to furnaces.
- 6. Briquettes placed in shovel and fed into crucibles.

Without Briquetting.

- 1. Cakes knocked from filter-frames to drying-car, care being taken not to break up cakes more than necessary; car wheeled to place, steam connected, dried, weighed entire, fluxes spread evenly over top of precipitate (without mixing), car run to furnace.

- 2. Precipitate and fluxes shoveled to crucibles.

Briquetting is a good thing, and it is also well to mix the fluxes intimately with the precipitate, but no one who has ever got some precipitate on his finger and tried to wipe it off on his overalls will dispute the statement that handling is a bad thing and spells 'loss'. Further, the precipitate at Dos Estrellas seems to melt as readily and to give as clean a slag without as with mixing. Care being taken not to break up the cakes as they fall from the press is almost as good as briquetting to prevent the precipitate from caking superficially and 'blowing' during fusion. The loss by dusting of such wet material is negligible. The flux generally used is:

Precipitate	100
Borax	15
Soda bicarbonate	8
Sand	4
Scrap wrought-iron in excess.	

The precipitate yields from 60 to 80% bullion. Coke is used as fuel at the two plants of the Dos Estrellas Co., but fuel oil by the El Oro and Mexico companies. Number 400 Dixon or 371A Morgan crucibles are used, each crucible holding about 86 kg. of mixed precipitate and fluxes. After fusion the upper portion of the molten mass in the crucible is poured into a conical mold with a clay-stopped tap-hole about three inches above the apex. The lower portion is poured into ingot molds. As soon as a shell of slag about 1/2 in. thick has formed in the 'tapping-mold' the clay plug is removed and the fluid central core is allowed to flow into another mold. A sample of the issuing slag is taken and granulated by being poured into water. The 'shells' from the conical molds, and the slag from the ingot-molds are remelted, poured into conical molds, and tapped as before. The cores are sacked and shipped at intervals to the smelter.

The slabs of bullion from the ingot-molds, together with the buttons from the tapping-molds, are remelted, no attempt being made at refining. On pouring the final bars two samples are taken: the first from the crucible after skimming the molten metal, and the second while pouring the bars. It is of interest to note that in 12 months, during which time a total of 35.23 metric tons of bullion was melted, the total difference in value of the bullion as indicated by the two samples was only \$1963.69. The sample taken while pouring gave the higher results.

The short zinc passing 20-mesh and resting on 60 carries from 5 to 10% of metal and is melted with the following flux:

Short-zinc	100
Borax	40
Soda	20
Sand	10
Lime	5

This flux gives a very fluid slag carrying about 40% zinc and exceedingly poor in gold and silver. The resultant metal carries about 20% zinc. Being so small a quantity in proportion to the total amount of bullion, the 'zinc metal' is added to the slabs of metal which come from the screened precipitate at the second melting.

LUNA COUNTY, NEW MEXICO.

Written for the MINING AND SCIENTIFIC PRESS
By E. McCORMICK.

Luna county, in the southwestern portion of New Mexico, comprises five districts, namely: Floridas, Tres Hermanas, Stonewall, Cooks, and Victorio, all in the vicinity of Deming, where a custom lead-smelter is in operation, the latter two districts being its chief feeder, although other portions of the territory, especially Magdalena, are drawn on from time to time, as necessity warrants. In the eighties all these districts except the Stonewall were productive, especially Cooks and Victorio.

Florida is 12 miles southeast of Deming, isolated and surrounded by the great alluvial plain. The rock mass is granite, porphyry, and limestone. The ore occurs along the contact and in the lime, and as found comprises carbonates and sulphides of lead and copper, both carrying a little silver. Nothing but surface mining has as yet been attempted, due no doubt to the limited capital of the companies operating. Of late, copper has been receiving the most attention, the latest find being in the porphyry near the lime contact. To date the district has been credited with approximately \$75,000, of which \$60,000 was extracted previous to 1885.

Tres Hermanas is an alluvial plain extending for 25 miles south of Deming. It is broken by a cluster of three peaks from which it derives its name, meaning 'three sisters.' The formation and the ores are identical to those found at Florida. Here the Carboniferous series flank the range, being supported by the igneous members beneath. All development has shown the deposits to be only on the surface. The ores are principally lead carbonate with an occasional pocket of what is locally known as lerchenite, no doubt hydrozincite. Here again we find development only in initial stages, although the district is well mineralized and worthy of investigation.

So far, the Cincinnati group is the only one of any prominence; it has produced material to the value of \$125,000.

Stonewall is a district 35 miles southwest of Deming, and is now dormant. In fact, but little development was ever attempted, the gold ores being of low tenor.

Cooks is 20 miles north of Deming, and is reached either by wagon, trail, or railroad. It derives its name from one Philip Cook, said to be the first white man to have scaled it. It is one of the most conspicuous landmarks of the county, towering to a height of over 12,000 ft. The mountain is mainly of eruptive rock, flanked by Carboniferous limestone. The mineralization occurs along the plane of contact, the chief deposits being in the limestone. The important mines are those belonging to the American Smelting & Refining Co., namely the Graphic and the Summit. The former was considered a great property years ago, having produced in the neighborhood of \$2,500,000, but of late they have reached the sulphide zone and are operating in an indifferent manner. The same can be said of the Graphic, which has a shaft 635 ft. deep, the deepest in the district, which

is also idle at present. A large deposit of fluorite exists which will no doubt in time find a market, lack of transportation at present preventing. Cerussite, plattnerite, and galena are the principal minerals found. Discoveries in the line of extensive bodies of low-grade lead-zinc sulphides have been exploited, but water is lacking, so experiments on dry concentration are under way. Should this prove successful it would revolutionize the camp, as the carbonates are almost exhausted. Records credit the district with the handsome production of \$4,000,000.

Victorio district is situated 24 miles west of Deming, and at present is the most prominent camp in the county. It derives its name from being one of the chief haunts of the Apache Indian chief, Victorio. This district has produced in the neighborhood of \$2,500,000, and is favorably situated for economic mining. Here again we find limestone intersected by reefs and dikes of eruptive rock. The ores consist of galena, cerussite, and anglesite, hübnerite, and scheelite also occurring but only in very limited amounts. The orebodies were undoubtedly formed by infiltration, the mass being well mineralized, and the ore-shoots regular. They offer good indications for deep-seated deposits. On the whole, the county seems to be well endowed with lead which must shortly command the attention of investors.
